A CONFORMING FINITE ELEMENT METHOD
WITH LAGRANGE MULTIPLIERS
FOR THE BIHARMONIC PROBLEM (*)

by Juhani PITKARANTA (1)

Communicated by P.-A. RAVIART

Abstract — We consider a finite element method for solving the biharmonic problem
\[ \Delta^2 u = f \text{ in } \Omega, \quad \frac{\partial u}{\partial n} = 0 \text{ on } \partial \Omega, \Omega \subset \mathbb{R}^2, \partial \Omega \text{ smooth.} \]
We use the method of Lagrange multipliers to avoid the fulfillment of the Dirichlet boundary conditions in the subspaces. Assuming the interior subspaces to be defined in terms of Argyris triangles, we show how the boundary subspaces in the Lagrange multiplier method can be defined so as to achieve a convergence rate of optimal order.

Résumé — On considère une méthode d’éléments finis pour résoudre le problème biharmonique
\[ \Delta^2 u = f \text{ dans } \Omega, \quad \frac{\partial u}{\partial n} = 0 \text{ sur } \partial \Omega, \Omega \subset \mathbb{R}^2, \partial \Omega \text{ régulier.} \]
On utilise la méthode des multiplicateurs de Lagrange pour éviter d’avoir à satisfaire les conditions aux limites de Dirichlet dans les sous-espaces. Supposant les sous-espaces « à l’intérieur » définis à l’aide de triangles d’Argyris, on montre comment définir les sous-espaces « à la frontière » afin d’obtenir un ordre de convergence d’ordre optimal.

1. INTRODUCTION

Let \( \Omega \) be a bounded, simply connected plane domain with a smooth boundary \( \partial \Omega \). We consider a high-order displacement finite element method for the solution of the biharmonic problem

\[ \Delta^2 u = f \text{ in } \Omega, \quad \frac{\partial u}{\partial n} = 0 \text{ on } \partial \Omega, \]

where \( f \) is some given function defined on \( \Omega \). In our approximation method the fulfillment of the Dirichlet boundary conditions in the finite element subspaces is avoided by using Lagrange multipliers. Thus, our approach is an analogue of the finite element method with Lagrange multipliers for solving the Dirichlet problem for a second-order elliptic equation, see [1, 6, 7, 8]. Besides avoiding the boundary conditions we get here independent approximations for

\[ \Delta u \big|_{\partial \Omega} \quad \text{and} \quad \frac{\partial}{\partial n} \Delta u \big|_{\partial \Omega}, \]

which is sometimes of physical interest.

We consider in detail an approximation where the approximate solution of (1.1) is sought in a finite element space constructed by means of Argyris triangles [4]. We show how the boundary subspaces in the Lagrange multipliers method can be constructed so as to achieve a convergence rate of optimal order. Our method of proof is analogous to that used in [7]: we introduce a norm depending on the finite element partitioning and show that a quasioptimal errors estimate can be obtained in this norm.

2. THE APPROXIMATION METHOD

For \( \Omega \subset R^2 \), \( \partial \Omega \) smooth, we use the symbol \( H^m(\Omega) \), \( m \geq 0 \), for a Sobolev space in its usual meaning. For non-integral \( s \), \( s \geq 0 \), one defines \( H^s(\Omega) \) by interpolation, and for \( s < 0 \), \( H^s(\Omega) \) is defined as the dual of \( H^{-s}(\Omega) \) [5]. We also denote by \( |D^k u|^2 \) the sum of the squares of all the \( k \)-th order derivatives of \( u \), \( u \) defined on \( \Omega \).

To define Sobolev spaces on the boundary, note that, since \( \partial \Omega \) is a closed smooth curve, there exist the smooth periodic functions \( J_1(t) \) and \( J_2(t) \), \( t \in R^1 \), with period of length unity, such that \( J(t) = (J_1(t), J_2(t)) \) defines a 1-1 mapping of \((0, 1)\) onto \( \partial \Omega \). Assuming \( J \) is such a mapping, we can define \( H^s(\partial \Omega) \), \( s \geq 0 \), as the closure of the set of all smooth functions on \( \partial \Omega \) in the norm

\[
\| \Psi \|_{H^s(\partial \Omega)} = \| \varphi \|_{H^s(0, 1)}, \quad \varphi(t) = \psi(J(t)).
\]

We consider the following weak formulation of problem (1.1): Find a triple \( (u, \psi, \varphi) \in H^2(\Omega) \times L_2(\partial \Omega) \times L_2(\partial \Omega) \) such that

\[
B(u, \psi, \varphi; v, \xi, \eta) = \int_{\Omega} f v dx
\]

for all \( (v, \xi, \eta) \in H^2(\Omega) \times L_2(\partial \Omega) \times L_2(\partial \Omega) \),

where

\[
B(u, \psi, \varphi; v, \xi, \eta) = \int_{\Omega} \Delta u \Delta v dx + \int_{\partial \Omega} \left( \frac{\partial u}{\partial n} \xi + u \eta + \frac{\partial v}{\partial n} \psi + v \varphi \right) ds.
\]

If \( u \) is the solution of problem (1.1) for \( f \) sufficiently smooth, then the triple \( (u, -\Delta u \big|_{\partial \Omega}, (\partial / \partial n) \Delta u \big|_{\partial \Omega}) \) is the solution of (2.1). Noting that the weak solution of (1.1) in \( H^2(\Omega) \) satisfies (cf. [5]):

\[
\| u \|_{H^{s+1}(\Omega)} + \| \Delta u \|_{\partial \Omega} \leq C \| f \|_{H^s(\Omega)}, \quad s > -\frac{1}{2}, \quad (2.3)
\]

we conclude that the assumption \( f \in H^s(\Omega), s > -1/2 \), suffices for the solvability of (2.1).
If $M^h \subset H^2 (\Omega), U^h \subset L_2 (\partial \Omega), V^h \subset L_2 (\partial \Omega)$ are finite-dimensional subspaces, one can define the approximate solution of (2.1) as the triple $(u_h, \psi_h, \varphi_h) \in M^h \times U^h \times V^h$ such that

$$B(u_h, \psi_h, \varphi_h; \nu, \xi, \eta) = \int_{\Omega} f \nu dx \quad (2.4)$$

for all $(\nu, \xi, \eta) \in M^h \times U^h \times V^h$.

We define first the subspaces $M^h$. To this end, let $\{ \Pi_h \}_{0 < h < 1}$ be a family of partitionings of $\Omega$ into disjoint open subsets $T_i$ such that each $T_i \in \Pi^h$ is either a triangle, or a deformed triangle with one curved side on $\partial \Omega$. We assume that the partitionings are quasiuniform, i.e., the diameters of all the triangles in $\Pi^h$ are proportional to $h$, and each $T \in \Pi^h$ contains a sphere of radius proportional to $h$ (the minimal angle condition). Now let $M^h$ be a finite-dimensional space of functions defined on $\Omega$ such that (i) for each $v \in M^h$ and $T \in \Pi^h$, $v |_T$ is a polynomial of degree $\leq 5$, (ii) $M^h \subset H^2 (\Omega)$, (iii) $D^2 v$ is continuous at the vertices of the triangulation $\Pi^h$.

The space $M^h$ can be set up by means of Argyris triangles [4]; for $h$ small enough, each $v \in M^h$ is defined uniquely by the values of $D^k v$, $k = 0, 1, 2$ at the vertices of the triangulation $\Pi^h$ and by the values of $\partial^2 v/\partial n$ at the midpoints of the sides of the triangles in $\Pi^h$.

To define the spaces $U^h$ and $V^h$, let $\{ x_1, \ldots, x_v \}$ be set of vertices of the triangulation $\Pi^h$ on $\partial \Omega$ and let

$$t_i = J^{-1} (x_i), \quad i = 1, \ldots, v,$$

$$I_i = (t_{i+1}, t_i), \quad i = 1, \ldots, v-1,$$

with $J$ as above. We let $N^h$ denote the third-degree Hermitean finite element space associated to the partitioning $\{ I_i \}^{-1}$ of $[0, 1]$, i.e., $N^h$ consists of continuously differentiable functions $\varphi (t)$ such that $\varphi |_{I_i}$ is a polynomial of degree $\leq 3$ for all $i$. We further set $N_0^h = \{ \varphi \in N^h, \varphi (0) = \varphi (1), \varphi ' (0) = \varphi ' (1) \}$ and define

$$U^h = V^h = \{ \psi; \psi (J (t)) = \theta (t) \in N_0^h \}.$$

3. RATE OF CONVERGENCE

We start by introducing on $H^2 (\Omega) \times L_2 (\partial \Omega) \times L_2 (\partial \Omega)$ the norm

$$|| (u, \psi, \varphi) ||^2_k = \int_{\Omega} | \Delta u |^2 dx + h^{-1} \int_{\partial \Omega} \left| \frac{\partial u}{\partial n} \right|^2 ds + h^{-3} \int_{\partial \Omega} u^2 ds + \int_{\partial \Omega} \psi^2 ds + h^3 \int_{\partial \Omega} \varphi^2 ds.$$

This is a norm, since the only harmonic function satisfying $u = 0$ on $\partial \Omega$ is zero. Our aim is to prove the following theorem.
THEOREM 1: Let \((u, \psi, \varphi) \in H^2(\Omega) \times L_2(\partial\Omega) \times L_2(\partial\Omega)\) be the solution of problem (1.2) and let \(M^h, U^h, V^h\) be defined as above. Then if \(h\) is small enough, problem (2.4) has a unique solution \((u_h, \psi_h, \varphi_h) \in M^h \times U^h \times V^h\) and there exists a constant \(C\) independent of \(h\) such that
\[
\| (u - u_h, \psi - \psi_h, \varphi - \varphi_h) \|_h \leq C \min_{(\xi, \eta) \in M^h \times U^h \times V^h} \| (u - v, \psi - \xi, \varphi - \eta) \|_h.
\]

The proof is based on the following two results.

PROPOSITION 1: Let \(v \in M^h\) be such that
\[
\begin{align*}
\int_{\partial\Omega} \frac{\partial v}{\partial n} \xi \, ds = 0, & \quad \forall \xi \in U^h, \\
\int_{\partial\Omega} v \eta \, ds = 0, & \quad \forall \eta \in V^h.
\end{align*}
\]
(3.1)

Then if \(h\) is small enough, there is a constant \(C\) independent of \(h\) such that
\[
h^{-1} \int_{\partial\Omega} \left| \frac{\partial v}{\partial n} \right|^2 \, ds + h^{-3} \int_{\Omega} v^2 \, ds \leq C \int_{\Omega} |\Delta v|^2 \, dx.
\]

PROPOSITION 2: For all \((\xi, \eta) \in U^h \times V^h\), \(h\) sufficiently small, there exists \(v \in M^h\) such that
\[
\int_{\partial\Omega} \left( \frac{\partial v}{\partial n} \xi + v \eta \right) \, ds \geq h \int_{\partial\Omega} \xi^2 \, ds + h^3 \int_{\partial\Omega} \eta^2 \, ds
\]
and
\[
\int_{\Omega} |\Delta v|^2 \, dx + h^{-1} \int_{\partial\Omega} \left| \frac{\partial v}{\partial n} \right|^2 \, ds + h^{-3} \int_{\Omega} v^2 \, ds \leq C \left\{ h \int_{\partial\Omega} \xi^2 \, ds + h^3 \int_{\partial\Omega} \eta^2 \, ds \right\},
\]
where \(C\) is independent of \(h\).

For a while, assume that the above propositions are true. Then we conclude, by comparing the propositions with the stability conditions of abstract Lagrange multiplier methods, as given in [3], that the bilinear form \(B\) of (2.2) satisfies
\[
\inf_{(u, \psi, \varphi) \in M^h \times U^h \times V^h} \sup_{(\xi, \eta) \in M^h \times U^h \times V^h} \frac{B(u, \psi, \varphi; v, \xi, \eta)}{\| (u, \psi, \varphi) \|_h \| (v, \xi, \eta) \|_h} \geq C > 0,
\]
(3.2)
where \(C\) is independent of \(h\). On the other hand, we note that \(B\) also satisfies
\[
|B(u, \psi, \varphi; v, \xi, \eta)| \leq \| (u, \psi, \varphi) \|_h \| (v, \xi, \eta) \|_h,
\]
(3.3)
for all \((u, \psi, \varphi), (v, \xi, \eta) \in H^2(\Omega) \times L_2(\partial\Omega) \times L_2(\partial\Omega)\).
The assertion of theorem 1 now follows from (3.2) and (3.3) by classical reasoning (see [2], pp. 186-188). □

Proof of proposition 1: Let \( \Gamma_k \) be any connected subset of \( \partial \Omega \) such that \( \Gamma_k \) is the union of \( k \) curved sides of triangles in \( \Pi^h \), and let \( S_k \subset \overline{\Omega} \) be the union of closed triangles \( T \in \Pi^h \) that either have a side \( \Gamma \subset \Gamma_k \) or have one vertex on \( \Gamma_k \). We set

\[
Q_k = \{ v|_{S_k} \mid v \in M^h \}.
\]

We further let \( A \) be a scaling mapping,

\[
A(x) = h^{-1} x, \quad x \in \mathbb{R}^2,
\]

and write

\[
\hat{S}_k = A(S_k), \quad \hat{\Gamma}_k = A(\Gamma_k),
\]

\[
\hat{Q}_k = \{ \hat{v} \mid \hat{v}(h^{-1} x) = v(x) \in O_k, x \in S_k \}.
\]

Let us first assume that \( \Gamma_k \) is a segment of a straight line and that the mapping \( J : [0, 1] \to \partial \Omega \) introduced in section 2 is locally of the simple form

\[
x \in \Gamma_k \Rightarrow x = J(t) = a + bt,
\]

where \( a, b \in \mathbb{R}^2 \) are some constant vectors. In this case the space

\[
\hat{X}_k = \{ \varphi(x) \mid \varphi(h^{-1} x) = \varphi_0(x) \in U^h |_{\Gamma_i} = V^h |_{\hat{\Gamma}_i}, x \in \Gamma_k \}
\]

is simply the third-order Hermitean finite element space associated to the partitioning of \( \Gamma_k \) that is induced by the triangulation

\[
\hat{\Pi}^h = \{ \hat{T}; \hat{T} = A(T), T \in \Pi^a \}.
\]

We let \( \{ \xi_i \} \) denote the set of ordinary local basis functions of \( \hat{X}_k \) with \( \| \xi_i \|_{L^2(\Gamma)} = 1 \), and let \( \Lambda_k \) be the index set such that if \( i \in \Lambda_k \), then \( \xi_i \) and its tangential derivative on \( \Gamma_k \) vanish at the endpoints of \( \Gamma_k \). Obviously, if \( m_k \) is the number of vertices of \( \hat{\Pi}^h \) in the interior of \( \hat{\Gamma}_k \), then \( \text{card} (\Lambda_k) = 2 m_k \).

In the above notation, let us define on \( \hat{Q}_k \) the seminorm \( \cdot |_{\hat{Q}_k} \) as

\[
|z|_{\hat{Q}_k}^2 = \int_{\hat{S}_k} |\Delta z|^2 dx + \sum_{i \in \Lambda_k} \left( \int_{\hat{\Gamma}_i} \frac{\partial^2 z}{\partial n} ds \right)^2 + \sum_{i \in \Lambda_k} \left( \int_{\hat{F}_i} \xi_i z ds \right)^2.
\]

Then we have:

**Lemma 1:** If \( k \) is large enough, \( \cdot |_{\hat{Q}_k} \) is a norm on \( \hat{Q}_k \).

**Proof:** Let \( z \in \hat{Q}_k \) be such that \( |z|_{\hat{Q}_k} = 0 \). We show first that \( z \) is a harmonic polynomial (of degree \( \leq 5 \)). To this end, let us number the triangles \( \hat{T} \in \hat{\Pi}^h \), \( \hat{T} \subset \hat{S}_k \), from 1 to \( l \) in such a way that \( \hat{T}_i \) and \( \hat{T}_{i+1} \) have a common side for
This is possible by our definition of $S_k$. Let $p_i$ be a polynomial of degree $\leq 5$ such that $z|_{\partial S_i} = p_i$. Then since $|z|_{\partial S_i} = 0$, $p_i$ is a harmonic polynomial. Further, since $z$ and $\partial z/\partial n$ are continuous, we conclude that $q_i = p_i - p_{i+1}$ is a harmonic polynomial satisfying $q_i = \partial q_i/\partial n = 0$ on the common side of $T_i$ and $T_{i+1}$. But then $q_i = 0$. Hence, there is a harmonic polynomial $p$ such that $z = p$ on $\hat{S}_k$.

We now have that $z$ is a polynomial of degree $\leq 5$ satisfying

$$\int_{\Gamma_k} \xi_i z \, ds = \int_{\Gamma_k} \xi_i \frac{\partial z}{\partial n} \, ds = 0, \quad i \in \Lambda_k.$$ 

Since $\text{card}(\Lambda_k)$ increases linearly with $k$, it is obvious that for $k$ large enough we necessarily have $z = \partial z/\partial n = 0$ on $\hat{\Gamma}_k$. But $z$ was a harmonic polynomial, so $z = 0$. □

From lemma 1 we have in particular that

$$\|z\|_{H^1(S_k)}^2 \leq C \left\{ \int_{S_k} |\Delta z|^2 \, dx + \sum_{i \in \Lambda_k} \left| \int_{\Gamma_k} \xi_i \frac{\partial z}{\partial n} \, ds \right|^2 + \sum_{i \in \Lambda_k} \left( \int_{\Gamma_k} \xi_i z \, ds \right)^2 \right\}, \quad z \in \hat{Q}_k, \quad k \geq k_0, \quad (3.4)$$

where $C$ depends on $\hat{Q}_k$. Now it is easy to see, arguing by contradiction, that whenever the triangles composing $\hat{S}_k$ satisfy the minimal angle condition, $(3.4)$ holds uniformly for all $\hat{S}_k$ constructed as above (with straight $\hat{\Gamma}_k$), with $C$ depending only on the constant in the minimal angle condition and on $k$. (Note that, by the minimal angle condition, the number of triangles $\hat{T} \in \hat{\Gamma}^h$ that touch $\hat{\Gamma}_k$ is at most a finite multiple of $k$.)

The next step of the proof is to verify that, for $h$ small enough, $(3.4)$ also holds when the actual curvature of $\hat{\Gamma}_k$ is taken into account. To this end, consider a given $\hat{\Gamma}_k$, $\hat{S}_k$ and choose an appropriate coordinate system $\{x_1, x_2\}$ to represent $\hat{\Gamma}_k$ as

$$\hat{\Gamma}_k = \{(x_1, x_2) \mid x_2 = \theta(x_1), \ x_1 \in I = [0, d]\},$$

where $\theta(0) = \theta(d) = 0$. Since $\partial \Omega$ is smooth, we may assume that if $h$ is small enough, then $\theta$ also satisfies

$$|\theta'(x_1)| \leq Ch, \quad x_1 \in I, \quad (3.5)$$

where $C$ depends only on $\Omega$ for fixed $k$.

We associate to each triangle $\hat{T} \in \hat{\Gamma}^h$, $\hat{T} \subset \hat{S}_k$, another triangle $\hat{T}'$ as follows. Let $\hat{T}$ have the vertices $x^k$, $k = 1, 2, 3$. Then $\hat{T}'$ is defined as a triangle with straight sides and with the vertices $y^k$ such that if $x^k \notin \hat{\Gamma}_k$, then $y^k = x^k$ and if $x^k = (x^k_1$, $x^k_2)$ then $y^k = (x^k_1 - h \theta'$, $x^k_2)$.
\[ \theta(x^k) \in \hat{T}^k, \text{ then } y^k = (x^k, 0). \] We denote the union of the closed triangles \( \hat{T}^* \) by \( \hat{S}^* \) and set \( \hat{S}^k = \{(x_1, x_2); x_1 \in I, x_2 = 0\} \). We further associate to \( \hat{S}^* \) and \( \hat{S}^k \) the spaces \( \hat{Q}^* \) and \( \hat{X}^* \) as above and let \( \{\xi_i\}_{i \in A_k} \) denote the set of local basis functions for \( \hat{X}^* \) such that \( \xi_i \) and \( d\xi_i/dx_1 \) vanish at the end-points of \( \hat{T}^k \).

Noting that we have

\[
\text{dist}\{x, \partial \hat{T}\} \leq Ch, \quad x \in \partial \hat{T},
\]

where \( C \) is independent of the triangle \( \hat{T} \), we conclude that the triangles \( \hat{T}^* \) satisfy the minimal angle condition if \( h \) is sufficiently small. Hence, we have from (3.4) that

\[
\begin{align*}
\|z\|_{H^1(\Sigma)}^2 & \leq C \left\{ \int_{\Sigma} |\Delta z|^2 \, dx + \sum_{i \in A_k} \left( \int_{\hat{T}^i} |\xi_i \frac{\partial z}{\partial n}| \, ds \right)^2 + \sum_{i \in A_k} \left( \int_{\hat{T}^i} \xi_i \, ds \right)^2 \right\}, \\
n & \quad z \in \hat{Q}^*, \quad k \geq k_0.
\end{align*}
\]

Now we need the following technical lemma.

**Lemma 2:** For any \( z \in \hat{Q}^* \) and \( \bar{\Phi} = \bar{\phi}(x_1) \in \hat{X}^* \) there exists \( \tilde{z} \in \hat{Q}^* \) and \( \phi \in \hat{X}^* \) such that

\[
\begin{align*}
\|\Delta z\|_{L^2(\Sigma)}^2 & = \|\Delta \tilde{z}\|_{L^2(\Sigma)}^2 \\
|\Phi(x_1, \theta(x_1)) - \bar{\phi}(x_1)| & \leq Ch \|\tilde{\Phi}\|_{L^\infty(\Sigma)}, \quad x_1 \in I,
\end{align*}
\]

where \( C \) is independent of \( z, \bar{\Phi}, x_1 \).

**Proof:** Let \( z \in \hat{Q}^* \) be given, and let \( \{a_i\} \) and \( \{a_i^*\} \) be the sets of the vertices of the triangulations of \( \hat{S}^k \) and \( \hat{S}^* \), respectively, and let \( \{b_i\} \) and \( \{b_i^*\} \) be the sets of the mid-points of the sides in the triangulations, with

\[
|a_i - a_i^*| \leq Ch, \quad |b_i - b_i^*| \leq Ch.
\]

Define \( \tilde{z} \) so that

\[
\frac{\partial^{l+m} \tilde{z}}{\partial x_1^l \partial x_2^m} (a_i) = \frac{\partial^{l+m} z}{\partial x_1^l \partial x_2^m} (a_1), \quad l + m \leq 2,
\]

and

\[
\frac{\partial \tilde{z}}{\partial n^*} (b_i) = \frac{\partial z}{\partial n} (b_i).
\]

Then if \( p \) and \( \bar{\Phi} \) are polynomials such that \( z|_{\hat{T}} = p \) and \( \tilde{z}|_{\hat{T}} = \bar{\phi} \), it is easy to verify from (3.6) that

\[
\begin{align*}
\|\Delta p\|_{L^2(\Sigma \cap \hat{T})} + \|\Delta \tilde{\Phi}\|_{L^2(\Sigma \cap \hat{T})} & \leq Ch \|p\|_{H^2(\Sigma)}, \\
\|\Delta p - \Delta \tilde{\Phi}\|_{L^2(\Sigma \cap \hat{T})} & \leq Ch \|p\|_{H^2(\Sigma)}.
\end{align*}
\]

From this the first part of the assertion follows easily.
Next, let $\Phi \in \tilde{X}_k$ be given and define $\Phi \in \tilde{X}_k$ so that if $(s, 0)$ is a vertex of the triangulation of $S_k'$, then
\[
\Phi(x_1, \theta(x_1)) = \tilde{\Phi}(x_1)
\]
and
\[
\frac{d}{dt} \Phi(x_1, \theta(x_1)) = \frac{d}{dx_1} \tilde{\Phi}(x_1) \quad \text{at} \quad x_1 = s,
\]
where $d/dt$ denotes the tangential differentiation on $\tilde{X}_k$. Recall from the definition of the subspace $U^h = V^h$ that if $\varphi \in \tilde{X}_k$, then
\[
\varphi(x_1, \theta(x_1)) = \varphi_0(x_1) = \eta(t(x_1)), \quad x_1 \in I,
\]
where $\eta$ is a piecewise polynomial function, and the relation $x_1 = x_1(t)$ is of the form
\[
x_1(t) = h^{-1} J_1(t), \quad t \in I_0 = [t_1, t_2], \quad |t_1 - t_2| \leq Ch,
\]
where $J_1$ is a smooth mapping. Write $J_1$ locally as
\[
J_1(t) = F(t) + \Delta(t),
\]
where $F$ is an affine mapping and $\Delta$ satisfies
\[
\Delta(t_1) = \Delta(t_2) = 0, \quad |\Delta(t)| \leq Ch^2, \quad t \in I_0.
\]
Taking the inverse we then have
\[
t = F^{-1}(hx_1) + \Delta_1(x_1), \quad x_1 \in I,
\]
with $\Delta_1(0) = \Delta_1(d) = 0, \quad |\Delta_1(x_1)| \leq Ch, \quad x_1 \in I$. Thus, we may write
\[
\varphi_0(x_1) = \eta(F^{-1}(hx_1) + \Delta_1(x_1))
\]
\[
= \eta(F^{-1}(hx_1)) + \Delta_2(x_1) = \eta_0(x_1) + \Delta_2(x_1), \quad x_1 \in I,
\]
where $\eta_0 \in \tilde{X}_k'$ and $\Delta_2$ satisfies
\[
|\Delta_2(x_1)| \leq Ch \|\eta\|_{L^\infty(I)} = Ch \|\Phi_0\|_{L^\infty(I)}.
\]
Setting $\varphi = \Phi$ and using (3.5) we now easily find that
\[
\Phi(x_1, \theta(x_1)) = \Phi_0(x_1) = \eta(x_1) + \Delta(x_1), \quad x_1 \in I,
\]
where
\[
|\Delta(x_1)| \leq Ch \|\Phi_0\|_{L^\infty(I)} \leq C_1 h \|\tilde{\Phi}\|_{L^\infty(I)}
\]
and $\eta \in \tilde{X}_k'$ is such that if $(s, 0)$ is a vertex of the triangulation of $S_k'$, then
\[
|\eta(s) - \tilde{\Phi}(s)| \leq Ch \|\tilde{\Phi}\|_{L^\infty(I)}
\]
and
\[
\frac{d}{dx_1} [\eta(x_1) - \tilde{\Phi}(x_1)]_{|x_1 = s} \leq Ch \|\tilde{\Phi}\|_{L^\infty(I)}.
\]
The second part of the assertion then follows. □

Now let \( z \in Q_k \) be given, let \( \tilde{z} \) be as in lemma 2, and let \( \xi_i \in X_k \) be local basis functions such that

\[
|\xi_i(x_1) - \xi_i(x_1, \theta(x_1))| \leq Ch \| \xi_i \|_{L^\infty} = Ch.
\]

Then lemma 2 and (3.7) imply:

\[
\| z \|_{H^1(S_k)}^2 \leq C \| \tilde{z} \|_{H^1(S_k)}^2 \\
\leq C_1 \left\{ \int_{S_k} |\Delta \tilde{z}|^2 \, dx + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i \frac{\partial \tilde{z}}{\partial x_2} \, dx_1 \right|^2 + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i \tilde{z} \, dx_1 \right| \right\} \\
\leq C_1 \left\{ \int_{S_k} |\Delta z|^2 \, dx + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i \frac{\partial z}{\partial n} \, ds \right|^2 + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i z \, ds \right| \right\} \\
+ C_2 h \left\{ \| z \|_{H^2(S_k)}^2 + \left| \int_{f_i} \frac{\partial z}{\partial n} \, ds \right|^2 + \int_{f_i} z^2 \, ds \right\}.
\]

On the other hand, within the assumptions made on \( S_k \) we certainly have:

\[
\int_{f_i} \frac{\partial z}{\partial n} \, ds + \int_{f_i} z^2 \, ds \leq C \| z \|_{H^2(S_k)}^2, \quad z \in Q_k.
\]

(3.8)

Thus, we conclude that (3.4) holds also in the case of a curved \( \Gamma_k \) if \( h \) is small enough.

As a consequence of (3.4) and (3.8) we have in particular that

\[
\int_{f_i} \frac{\partial z}{\partial n} \, ds + \int_{f_i} z^2 \, ds \leq C \left\{ \int_{S_k} |\Delta z|^2 \, dx + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i \frac{\partial z}{\partial n} \, ds \right|^2 + \sum_{i \in \Lambda_i} \left| \int_{f_i} \xi_i z \, ds \right| \right\}, \quad z \in Q_k, \quad k \geq k_0.
\]

(3.9)

Using this inequality it is now easy to complete the proof: Take \( v \in M^h \) to be such that (3.1) is satisfied, and choose a collection \( \{ S_k^{(j)}, \Gamma_k^{(j)} \}_{j=1}^v \), \( k \geq k_0 \), such that \( \bigcup_{j=1}^v \Gamma_k^{(j)} = \partial \Omega \) and for all \( j \), \( S_k^{(j)} \cap S_k^{(0)} = \emptyset \) for all except three values of \( l \). Then if \( v_j(x) = v(hx) \), \( x \in \tilde{S}_k^{(j)} = A(S_k^{(j)}) \),

we have, setting \( z = v_j \) in (3.9), that

\[
\int_{f_i^{(j)}} \xi_i \frac{\partial v_j}{\partial n} \, ds = \int_{f_i^{(j)}} \xi_i v_j \, ds = 0,
\]

and hence

\[
\int_{f_i^{(j)}} \left| \frac{\partial v_j}{\partial n} \right|^2 \, ds + \int_{f_i^{(j)}} v_j^2 \, ds \leq C \int_{S_k^{(j)}} |\Delta v_j|^2 \, dx, \quad j = 1, \ldots, v.
\]
Upon scaling scaling back to the original size we get
\[ h^{-1} \int_{\Gamma(v)} \left| \frac{\partial v}{\partial n} \right|^2 ds + h^{-3} \int_{\Gamma(v)} v^2 ds \leq C \int_{\delta \Gamma(v)} |\Delta v|^2 dx, \quad j = 1, \ldots, v. \]

Summing over \( j \), we now obtain the desired inequality, and the proof of proposition 1 is complete.

Proof of proposition 2: Let \((\xi, \eta) \in U^h \times V^h\) be given, let \( \{ x^1, \ldots, x^v \} \) be the set of vertices of the triangulation \( \Pi^h \) on \( \partial \Omega \), and let \( \{ y^1, \ldots, y^v \} \) be the set of midpoints of the sides on \( \partial \Omega \) of the triangles in \( \Pi^h \). We consider functions \( u, v \in M^h \), which satisfy
\[
\begin{align*}
    u_n(x^i) &= h \xi(x^i), \\
    u_t(x^i) &= h \xi_t(x^i), \\
    u_{nt}(x^i) &= h \xi_{tt}(x^i), \\
    v(x^i) &= h^3 \eta(x^i), \\
    v_t(x^i) &= h^3 \eta_t(x^i),
\end{align*}
\]

(3.10)

Here \( u_n \) and \( u_t \) are respectively the normal and the tangential derivative of \( u \) on \( \partial \Omega \).

Among the functions \( u, v \in M^h \) that satisfy (3.10), let \( u_0 \) and \( v_0 \) be those obtained by setting all the remaining degrees of freedom (in the Argyris triangles) equal to zero. We prove first some estimates for \( u_0, v_0 \) and \( w_0 = u_0 + v_0 \).

Lemma 3: If \( h \) is small enough, then
\[ \int_{\Omega} |\Delta w_0|^2 dx \leq C \left\{ h^{-1} \int_{\partial \Omega} \left| \frac{\partial w_0}{\partial n} \right|^2 ds + h^{-3} \int_{\partial \Omega} w_0^2 ds \right\}, \]

\[ + h^{-2} \left\| \frac{\partial u_0}{\partial n} \right\|_{L^2(\partial \Omega)} + h^{-2} \left\| \frac{\partial v_0}{\partial n} \right\|_{L^2(\partial \Omega)} \leq Ch \left\| \xi \right\|_{L^2(\partial \Omega)}, \]

\[ + \left\| u_0 \right\|_{L^2(\partial \Omega)} \leq Ch \left\| \eta \right\|_{L^2(\partial \Omega)}. \]

Proof: Let \( T \in \Pi^h \) be such that \( T \) has a curved side \( \Gamma \) on \( \partial \Omega \), let \( \hat{T} = A(T) \), \( \hat{\Gamma} = A(\Gamma) \), where \( A(x) = h^{-1} x, x \in R^2 \), and let \( \hat{v}(x) = v(hx) \) for \( v \) defined on \( T \) or \( \Gamma \).

We choose a coordinate system \( \{ x_1, x_2 \} \) so as to represent \( \hat{T} \) as
\[
\hat{T} = \{(x_1, x_2); x_2 = \theta(x_1), x_1 \in I = [0, d]\},
\]
\[ \theta(0) = \theta(d) = 0, \quad \theta'(x_1) \leq Ch, \quad x_1 \in I. \]

(3.11)

One can verify from (3.11) and from the minimal angle condition that if \( p \) is any polynomial of degree \( \leq 5 \), then
\[
\left| \frac{\partial^{k+l} p}{\partial x_1^k \partial x_2^l}(x_1, 0) - \frac{\partial^{k+l} p}{\partial t^k \partial n^l}(x_1, \theta(x_1)) \right| \leq Ch \left\| p \right\|_{H^2(\Gamma)}, \quad x_1 \in I, \quad k, l \geq 0. \]

(3.12)

RAIRO Analyse numérique/ Numerical Analysis
Further, since \( p(x_1, 0) \) and \( \partial p/\partial x_2(x_1, 0) \) are polynomials in \( x_1 \) of degree 5 and 4, respectively, we have, for some positive constants \( C_1 \) and \( C_2 \),
\[
C_1 \int_0^d |p(x_1, 0)|^2 \, dx_1 \geq \sum_{k=0}^2 \left\{ \left| \frac{\partial^k p}{\partial x_1^k}(0, 0) \right|^2 + \left| \frac{\partial^k p}{\partial x_1^k}(d, 0) \right|^2 \right\} 
\]
and
\[
C_1 \int_0^d \left| \frac{\partial p}{\partial x_2}(x_1, 0) \right|^2 \, dx_1 \geq \left| \frac{\partial p}{\partial x_2}(0, 0) \right|^2 + \left| \frac{\partial p}{\partial x_2}(d, 0) \right|^2 
+ \left| \frac{\partial p}{\partial x_2}(y_1, 0) \right|^2 + \left| \frac{\partial^2 p}{\partial x_1 \partial x_2}(0, 0) \right|^2 + \left| \frac{\partial^2 p}{\partial x_1 \partial x_2}(d, 0) \right|^2 
\]
\[
\geq C_2 \int_0^d \left| \frac{\partial p}{\partial x_2}(x_1, 0) \right|^2 \, dx_1, \tag{3.13}
\]
where \((y_1, \theta(y_1))\) is the midpoint of \( \Gamma \).

We now apply the above inequalities in the particular case where \( p = \hat{w}_0 \). First, note that \( \hat{w}_0 \) is defined uniquely by the values of
\[
\frac{\partial \hat{w}_0}{\partial x_2}(y_1, 0), \quad \frac{\partial^{k+l} \hat{w}_0}{\partial x_1^k \partial x_2^l}(0, 0),
\]
and
\[
\frac{\partial^{k+l} \hat{w}_0}{\partial x_1^k \partial x_2^l}(d, 0), \quad k + l \leq 2,
\]
and that
\[
\frac{\partial^2 \hat{w}_0}{\partial n^2}(0, 0) = \frac{\partial^2 \hat{w}_0}{\partial t^2}(0, 0) = \frac{\partial^2 \hat{w}_0}{\partial n^2}(d, 0) = \frac{\partial^2 \hat{w}_0}{\partial t^2}(d, 0) = 0.
\]
Using (3.12) through (3.14) we then have
\[
\| \hat{w}_0 \|_{H^2(\Gamma)}^2 \leq C \left\{ \sum_{k=0}^2 \left[ |D^k \hat{w}_0(0, 0)|^2 
+ \left| D^k \hat{w}_0(d, 0) \right|^2 \right] \right\} 
\]
\[
\leq C_1 \left\{ \int_0^d \left| \frac{\partial \hat{w}_0}{\partial x_2}(x_1, 0) \right|^2 \, dx_1 + \int_0^d \left| \hat{w}_0(x_1, 0) \right|^2 \, dx_1 \right\} 
+ C_2 h^2 \| \hat{w}_0 \|_{H^2(\Gamma)}^2 
\leq C_1 \left\{ \int_\Gamma \left| \frac{\partial \hat{w}_0}{\partial n} \right|^2 \, ds + \int_\Gamma \left| \hat{w}_0 \right|^2 \, ds \right\} + C_3 h^2 \| \hat{w}_0 \|_{H^2(\Gamma)}^2,
\]
and so, for $h$ small enough,

$$
\| \hat{w}_0 \|_{H^1(T)} \leq C \left\{ \int_T \left| \frac{\partial \hat{w}_0}{\partial n} \right|^2 ds + \int_T \hat{w}_0^2 ds \right\}.
$$

Next, let $p = \hat{u}_0$. Then (3.10) and (3.12) through (3.14) imply

$$
\| \hat{u}_0 \|_{L^2(T)} \leq Ch \| \hat{u}_0 \|_{H^1(T)} \leq C_1 h \left| \frac{\partial \hat{u}_0}{\partial n} \right|_{L^2(T)}.
$$

Further, using (3.10) and repeating some of the arguments used in the proof of lemma 2, we have

$$
\left\| \frac{\partial \hat{u}_0}{\partial n} \right\|_{L^2(T)} \leq Ch^2 \| \xi \|_{L^2(T)}.
$$

By a similar logic, one can verify that

$$
\left\| \frac{\partial \hat{v}_0}{\partial n} \right\|_{L^2(T)} \leq Ch \| \hat{v}_0 \|_{L^2(T)} \leq C_1 h^4 \| \hat{n} \|_{L^2(T)}.
$$

Consider finally a triangle $T \in \Pi^h$ which has only a vertex on $\partial \Omega$. Let this vertex be shared by the triangles $T_1, T_2 \in \Pi^h$, both of which have a side on $\partial \Omega$. Then if $\hat{T} = A(T), \hat{T}_1 = A(T_1), \hat{T}_2 = A(T_2)$, it is easy to verify from the definition of $w_0$ that

$$
\| \hat{w}_0 \|_{H^1(\hat{T})} \leq C \left\{ \| \hat{w}_0 \|_{H^1(\hat{T}_1)}^2 + \| \hat{w}_0 \|_{H^1(\hat{T}_2)}^2 \right\}.
$$

Upon scaling in the last five inequalities obtained above, summing over $T$ and $\Gamma$, and noting that $w_0$ vanishes on any triangle $T \in \Pi^h$ that does not touch $\partial \Omega$, the asserted inequalities follow.

In view of lemma 3, if we set $v = w_0$, the second inequality of proposition 2 is proved. To prove the first inequality, note first that we have

$$
\left\| \frac{\partial u_0}{\partial n} - h \xi \right\|_{L^2(\hat{\Gamma})} \leq Ch \| h \xi \|_{L^2(\hat{\Gamma})}.
$$

This follows again from local arguments similar to those used in the proof of lemma 2. Using this we have that, for $h$ small enough,

$$
\int_{\partial \Omega} \frac{\partial u_0}{\partial n} \xi ds \geq Ch \int_{\partial \Omega} \xi^2 ds, \quad C > 0. \quad (3.15)
$$

To continue, we need the following lemma. The proof is given in the Appendix.

**Lemma 4:** Let $p(t)$ be any polynomial of degree $\leq 3$, and let $q(t)$ be a polynomial of degree $\leq 5$ such that

$$
q(0) = p(0), \quad q'(0) = p'(0), \quad q(1) = p(1), \quad q'(1) = p'(1), \quad q''(0) = q''(1) = 0.
$$
Then
\[ \int_0^1 pq \, dt \geq C \int_0^1 p^2 \, dt, \quad C > 0. \]

Using lemma 4 and once again repeating arguments from the proof of lemma 2, we get that for \( h \) small enough,
\[ \int_{\partial \Omega} w_0 \, \eta \, ds \geq Ch^3 \int_{\partial \Omega} \eta^2 \, ds, \quad C \geq 0. \]  
(3.16)

Combining (3.15) and (3.16) with the inequalities of lemma 3 we now have
\[ \int_{\partial \Omega} \frac{\partial w_0}{\partial n} \xi \, ds + \int_{\partial \Omega} w_0 \, \eta \, ds \geq Ch \int_{\partial \Omega} \xi^2 \, ds + Ch^3 \int_{\partial \Omega} \eta^2 \, ds \\
+ \int_{\partial \Omega} \frac{\partial v_0}{\partial n} \xi \, ds + \int_{\partial \Omega} u_0 \, \eta \, ds \geq C \left( \frac{1}{2} C h \right) \left\{ h \int_{\partial \Omega} \xi^2 \, ds + h^3 \int_{\partial \Omega} \eta^2 \, ds \right\}, \quad C > 0. \]

This proves the first inequality in proposition 2, with \( v = w_0 \), \( h \) sufficiently small. The proof is then complete. \( \square \)

Using theorem 1, we can now evaluate the rate of convergence of the Lagrange multiplier method (2.4).

**Theorem 2:** Let \((u, \psi, \varphi)\) be the solution of (2.1) for \( f \in H^s(\Omega), s > -1/2, \) and let \((u_h, \psi_h, \varphi_h)\) be the solution of (2.4) with the subspaces \( M_h, U_h, V_h \) defined as above. Then we have the error bound
\[ \sum_{k=0}^2 h^{2k-4} \int_{\Omega} |D^k(u-u_h)|^2 \, dx + h^{-1} \int_{\partial \Omega} \left| \frac{\partial}{\partial n}(u-u_h) \right|^2 \, ds \\
+ h^{-3} \int_{\partial \Omega} |u-u_h|^2 \, ds + h^3 \int_{\partial \Omega} |\psi-\psi_h|^2 \, ds + h^3 \int_{\partial \Omega} |\varphi-\varphi_h|^2 \, ds \leq Ch^2 \mu \|f\|^2_{H^s(\Omega)}, \]
\[ \mu = \min \{4, s + 2\}. \]

**Proof:** For \( u \) defined on \( \Omega \) and sufficiently smooth, let \( \widetilde{u} \) be the interpolant of \( u \) on \( M_h \). Then we have, by classical results of approximation theory (cf. [4]), the estimates
\[ \sum_{k=0}^2 h^{2k-4} \int_{\Omega} |D^k(u-\widetilde{u})|^2 \, dx \leq Ch^2 s^{-4} \|u\|^2_{H^s(\Omega)}, \]
\[ u \in H^s(\Omega), \quad 3 < s \leq 6. \]
Reasoning by a local scaling argument analogous to that used in [7] one can also verify that
\[ h^{-1} \int_{\partial \Omega} \left| \frac{\partial}{\partial n} (u - \tilde{u}) \right|^2 ds + h^{-3} \int_{\partial \Omega} |u - \tilde{u}|^2 ds \]
\[ \leq C \sum_{k=0}^{2} h^{2k-4} \int_{\Delta} |D^k(u - \tilde{u})|^2 dx, \]
where \( \Delta \) is the union of the triangles in \( \Pi^h \) that have a side on \( \partial \Omega \).

On the other hand, by the definition of the space \( U^h = V^h \) and again by classical results of approximation theory, we have
\[ \min_{\xi \in U^h} \| \psi - \xi \|_{L^1(\partial \Omega)} \leq C h^s \| \psi \|_{H^s(\partial \Omega)}, \]
\[ \psi \in H^s(\partial \Omega), \quad 0 \leq s \leq 4. \]

Upon combining the above estimates with theorem 1 and with the a priori estimate (2.3) we have proved:
\[ \| (u - u_h, \psi - \psi_h, \varphi - \varphi_h) \|_h \leq C h^s \| f \|_{H^s(\Omega)}, \]
\[ s > - \frac{1}{2}, \quad \mu = \min \{ 4, s + 2 \}. \]

To complete the proof, we use the Aubin-Nitsche duality argument together with (2.3), (3.3), and the above approximation results to conclude that
\[ \| u - u_h \|_{L^1(\Omega)} \leq C h^2 \| (u - u_h, \psi - \psi_h, \varphi - \varphi_h) \|_h. \]
Finally, since partitioning \( \Pi^h \) is quasiuniform, we have the inverse estimates
\[ \int_{\Omega} |D^k(u - u_h)|^2 dx \leq C \left\{ h^{-2k} \| u - u_h \|^2_{L^1(\Omega)} + \min_{v \in M^k} \left\{ h^{-2k} \| u - v \|^2_{L^1(\Omega)} + \int_{\Omega} |D^k(u - v)|^2 dx \right\} \right\}, \]
\[ k = 1, 2. \]
Upon combining the last three estimates, the assertion of the theorem follows. \( \square \)

APPENDIX

PROOF OF LEMMA 4

Let

\[ p(t) = \sum_{i=0}^{3} \alpha_i t^i, \quad t \in [0, 1]. \]

Then the polynomial \( q(t) \) of degree \( \leq 5 \) which satisfies

\[
q(t_0) = p(t_0), \quad q'(t_0) = p'(t_0), \quad q''(t_0) = 0, \quad t_0 = 0, 1,
\]

is given by

\[
q(t) = \alpha_0 + \alpha_1 t + \alpha_2 (2 t^3 - t^4) + \alpha_3 (-2 t^3 + 6 t^4 - 3 t^5).
\]

We then have

\[
\int_0^1 pq \, dt = [\alpha]^T [A] [\alpha],
\]

where \([\alpha]^T = [\alpha_0, \ldots, \alpha_3]\) and the \(4 \times 4\) matrix \([A]\) is given by

\[
[A] = \begin{bmatrix}
1 & 1 & 19 & 9 \\
2 & 60 & 40 & \text{sym.} \\
3 & 120 & 70 & 4 \\
& & & 13 \\
& & & 21 \\
& & & 84 \\
& & & 11 \\
& & & 84 \\
\end{bmatrix}
\]

vol. 14, n°3, 1980
By a direct computation, the characteristic equation of $[A]$ can be written into the form
\[
\sum_{i=0}^{4} (-1)^i c_i \lambda_i^4 = 0, \quad c_i > 0
\]
Hence, all the eigenvalues of $[A]$ are positive. If in particular $\lambda_0 > 0$ is the smallest eigenvalue, we have
\[
\int_0^1 pq \, dt = [\alpha]^T [A] [\alpha] \geq \lambda_0 [\alpha]^T [\alpha] \geq \lambda_0 C \int_0^1 p^2 \, dt, \quad C > 0,
\]
which proves the assertion $\square$
