ABOUT ASYMPTOTIC APPROXIMATIONS IN THIN WAVEGUIDES

NICOLE TURBE\textsuperscript{1} AND LOUIS RATIER\textsuperscript{2}

Abstract. We study the propagation of electromagnetic waves in a guide the section of which is a thin annulus. Owing to the presence of a small parameter, explicit approximations of the TM and TE eigenmodes are obtained. The cases of smooth and non smooth boundaries are presented.

Received: July 8, 2003. Revised: April 5 and July 18, 2005.

1. INTRODUCTION

Physical studies often give rise to problems of applied mathematics. To obtain solutions of these problems, numerical methods are generally used. Beside this, an interesting field is that where asymptotic expansions can be operated. This work enters this field. The propagation in closed waveguides is studied. We assume that one of the two characteristic lengths of the section is small compared to the other: precisely, the transverse section of the guide is a thin annulus. Its thickness is the small parameter of the problem. We consider an electromagnetic waveguide and we formulate two assumptions: the electromagnetic material is homogeneous and the distance between the two curves of the boundary of the section is constant. Then, explicit expressions result from the Laplacian operator of the problem.

The paper is mainly divided into two parts. The first one is devoted to the study for a smooth boundary and the other to a boundary with angular points. Asymptotic results are compared, in both cases, with computed ones.

2. STATEMENT OF THE PROBLEM

Let us consider an electromagnetic cylindrical waveguide $\Omega \times \mathbb{R}$. The bounded section has a boundary $\partial \Omega$, constituted by two curves, $\Gamma_0$ and $\Gamma_1$ (Fig. 1). The distance between them is small compared to the diameter of the section $\Omega$.

\textbf{Keywords and phrases.} Closed thin waveguides, asymptotic approximations.
Along $\Gamma_0 \times \mathbb{R}$ and $\Gamma_1 \times \mathbb{R}$, the waveguide is in contact with a perfect infinite conductor. Let $(x_1, x_2, x_3)$ represents the Cartesian coordinates of a point of $\mathbb{R}^3$ and $(x_1, x_2)$ the transverse coordinates. An electromagnetic wave $\vec{E}(x) \exp[i(\omega t - \beta x_3)]$ propagates inside the guide. The real positive given parameter $\beta$ is the wave number in the direction $x_3$ of the propagation. Maxwell’s harmonic equations [1] govern the problem:

$$i \omega \varepsilon \vec{E} - \text{Rot}_\beta \vec{H} = 0, \quad i \omega \mu \vec{H} + \text{Rot}_\beta \vec{E} = 0 \quad \text{in } \Omega$$

$$\vec{E} \wedge \vec{N} = 0, \quad \vec{H} \wedge \vec{N} = 0 \quad \text{on } \partial \Omega,$$

$\vec{N}$ is a normal vector to $\partial \Omega$ and $\text{Rot}_\beta \vec{u}$ is the vector with the following components:

$$(u_{3,2} + i \beta u_2, -u_{3,1} - i \beta u_1, u_{2,1} - u_{1,2}) \quad \text{(the notation } u_{i,j} = \partial u_i / \partial x_j \text{ is used)}.$$ 

**Assumption 1.** We assume that the dielectric constant $\varepsilon$ and the magnetic permeability $\mu$ of the medium are real, positive constants.

We introduce real valued unknown fields [2]:

$$e_1 = E_1, \quad e_2 = E_2, \quad e_3 = i E_3, \quad h_1 = H_1, \quad h_2 = H_2, \quad h_3 = -i H_3 \quad (i^2 = -1).$$

The equations now can be written, with $\text{rot}_\beta = \text{Rot}_{i\beta}$:

$$\text{rot}_\beta \vec{u} = (u_{3,2} - \beta u_2, -u_{3,1} + \beta u_1, u_{2,1} - u_{1,2}) \quad (2.1)$$

$$\omega \varepsilon \vec{\varepsilon} = \text{rot}_\beta \vec{\varepsilon}, \quad \omega \mu \vec{\mu} = \text{rot}_\beta \vec{\mu}. \quad (2.2)$$

Eliminating the magnetic field $\vec{\mu}$, the problem in the electric field $\vec{\varepsilon}$ follows:

$$\text{rot}_{-\beta} (\text{rot}_\beta \vec{\varepsilon}) = \omega^2 \varepsilon \mu \vec{\varepsilon} \quad \text{in } \Omega \quad (2.3)$$

$$\vec{\varepsilon} \wedge \vec{N} = 0 \quad \text{on } \partial \Omega. \quad (2.4)$$

In a closed guide, for a given wave number $\beta$, there exists an infinite countable sequence of eigenfrequencies. The longitudinal and transversal fields problems provide them. Let us denote by $e_3$ and $e$ the longitudinal and transversal components of the electric field $\vec{\varepsilon}$. From (2.2), the relation $\text{div } e = \beta e_3$ results, with $\text{div } e = e_{1,1} + e_{2,2}$ and problem (2.3), (2.4) leads to a Dirichlet problem for $e_3$ and then to a problem for $e$:

$$\Delta e_3 + (\omega^2 \varepsilon \mu - \beta^2) e_3 = 0 \quad \text{in } \Omega \quad (2.5)$$

$$e_3 = 0 \quad \text{on } \partial \Omega. \quad (2.6)$$

$$\text{rot rot } e - (\omega^2 \varepsilon \mu - \beta^2) e = \beta \text{ grad } e_3 \quad \text{in } \Omega \quad (2.7)$$

$$e \wedge \vec{N} \text{ on } \partial \Omega. \quad (2.8)$$

This last boundary condition is associated with the operator $\text{rot rot}$, which is defined by its two components:

$$\text{rot rot } u = (u_{2,12} - u_{1,22}, u_{1,21} - u_{2,11}).$$
Related to the distance between $\Gamma_0$ and $\Gamma_1$, a small parameter $\eta$ allows approximations of the eigenfrequencies and the eigenfunctions.

3. Approximations for a $C^1$ boundary

3.1. Local coordinates

We introduce local non dimensional coordinates. Two characteristic lengths are to be considered: the diameter $l$ and the thickness $\eta l$ of $\Omega$, $\eta$ being a small parameter ($\eta \ll 1$). We denote by $s l$ the arc length parameter along the boundary $\Gamma_0$. And a point $P$ is located in $\Omega$ from a point $M$ on $\Gamma_0$ by: $PM = \eta l \nu \vec{n}$, where $\vec{n} = \vec{\nu}$ is the unitary normal vector to $\Gamma_0$ in $M$, oriented to the interior of $\Omega$ (Fig. 2).

![Figure 2. Local basis.](image)

**Assumption 2.** We assume that the equation of $\Gamma_0$ (resp. $\Gamma_1$) is $\nu = 0$ (resp. $\nu = 1$).

Let $\vec{\tau}$ be the tangential vector to $\Gamma_0$ in $M$: $\vec{\tau} = \vec{\tau}_3 \wedge \vec{n}$. For this plane curve, the Frenet-Serret formulas hold:

$$d\vec{n} = R^{-1}ds \vec{\tau}, \quad d\vec{\tau} = -R^{-1}ds \vec{n},$$  \hspace{1cm} (3.1)

where $R(s)$ is the non dimensional radius of curvature of $\Gamma_0$ in $M$. Then, from $OP = OM + MP$, we have:

$$d\vec{P} = \eta l d\nu \vec{n} + \sigma l ds \vec{\tau}; \quad \sigma = 1 + \eta \nu R^{-1}.$$  \hspace{1cm} (3.2)

Owing to relations (3.1) and (3.2), we can express, on the local basis, the operators $\text{grad}$ and $\Delta$, for a scalar function $p(\nu, s)$. The gradient of $p$ is defined by: $\text{grad} p = \frac{1}{\eta l} \frac{\partial p}{\partial \nu} \vec{n} + \frac{1}{\sigma l} \frac{\partial p}{\partial s} \vec{\tau}$; $\Delta p = \frac{1}{\eta l^2} \left( \frac{\partial^2 p}{\partial \nu^2} + \frac{\eta}{\sigma l} \frac{\partial p}{\partial \nu} + \frac{\eta^2}{\sigma^2 l^2} \frac{\partial^2 p}{\partial s^2} + \eta R' \nu \frac{\partial p}{\partial \nu} + \eta \nu R^2 \frac{\partial p}{\partial \nu} \right)$.  \hspace{1cm} (3.3)

In (3.3-2), $R'$ denotes the derivative $dR/ds$.

3.2. Transverse magnetic (TM) wave: $e_3 \neq 0$, $h_3 = 0$

With the new variables, the equation for the longitudinal electric field problem becomes:

$$\frac{\partial^2 e_3}{\partial \nu^2} + \frac{\eta}{\sigma R} \frac{\partial e_3}{\partial \nu} + \frac{\eta^2}{\sigma^2} \frac{\partial^2 e_3}{\partial s^2} + \frac{\eta^3}{\sigma^3 R} \nu R' \frac{\partial e_3}{\partial \nu} + \eta^2 l^2 (\omega^2 \varepsilon \mu - \beta^2) e_3 = 0 \quad \text{in} \ \Omega$$  \hspace{1cm} (3.4)

$$e_3 = 0 \quad \text{on} \ \partial \Omega.$$  \hspace{1cm} (3.5)

The presence of the parameter $\eta$ involves that the eigenelements depend on the parameter $\eta$. Let us denote: $e_3 = w_\eta$, $\eta l \sqrt{\omega^2 \varepsilon \mu - \beta^2} = \alpha_\eta$. For small $\eta$, we search expansions of the solution:

$$w_\eta = w_0 + \eta w_1 + \eta^2 w_2 + \ldots; \quad \alpha_\eta = \alpha_0 + \eta \alpha_1 + \eta^2 \alpha_2 + \ldots$$  \hspace{1cm} (3.6)

We insert these expressions in (3.4), (3.5) (with Assumption 2) and we identify the successive terms, powers of $\eta$, assuming that is $R$ is $O(1)$ compared to $\eta$. 

From the term \( \eta^0 \), we obtain the homogeneous problem for \( w_0 \):

\[
\frac{\partial^2 w_0}{\partial \nu^2} + \alpha_0^2 w_0 = 0 \quad \text{for} \quad 0 < \nu < 1
\]

\[
w_0 = 0 \quad \text{on} \quad \nu = 0, \; \nu = 1.
\]

(3.7)

(3.8)

Its solution is:

\[
\alpha_0 = \alpha_0(n) = n\pi \quad (n \in \mathbb{N}^*); \quad w_0(\nu, s) = C_0(s) \sin(\alpha_0 \nu).
\]

(3.9)

To determine the function \( C_0 \), we must go on.

From the term \( \eta^1 \), we obtain a non homogeneous problem for \( w_1 \):

\[
\frac{\partial^2 w_1}{\partial \nu^2} + \alpha_0^2 w_1 = -\frac{1}{R} \frac{\partial w_0}{\partial \nu} - 2\alpha_0 \alpha_1 w_0 \quad \text{for} \quad 0 < \nu < 1
\]

\[
w_1 = 0 \quad \text{on} \quad \nu = 0, \; \nu = 1.
\]

(3.10)

(3.11)

The scalar product in \( L^2(0, 1) \) of equation (3.10) by \( \sin(\alpha_0 \nu) \) leads, after integrations by parts, to:

\[
\alpha_1 = 0.
\]

(3.12)

Then, we obtain:

\[
w_1(\nu, s) = C_1(s) \sin(\alpha_0 \nu) - \frac{C_0(s)}{2R} \nu \sin(\alpha_0 \nu).
\]

(3.13)

The term \( \eta^2 \) gives \( \alpha_2 \) and the function \( C_0 \). The problem to be solved is, for \( 0 < \nu < 1 \):

\[
\frac{\partial^2 w_2}{\partial \nu^2} + \alpha_0^2 w_2 = -\frac{1}{R} \frac{\partial w_1}{\partial \nu} + \nu \frac{\partial w_0}{\partial \nu^2} - \frac{\partial^2 w_0}{\partial s^2} - (\alpha_1^2 + 2\alpha_0 \alpha_2) w_0 - 2\alpha_0 \alpha_1 w_1
\]

\[
w_2 = 0 \quad \text{on} \quad \nu = 0, \; \nu = 1.
\]

(3.14)

(3.15)

With (3.12), from the scalar product of equation (3.12) by \( \sin(\alpha_0 \nu) \) and integrations by parts, we obtain the differential equation:

\[
\frac{d^2 C_0}{ds^2} + \left( \frac{1}{4R^2} + 2\alpha_0 \alpha_2 \right) C_0 = 0.
\]

(3.16)

Then, we get the term \( w_2 \):

\[
w_2(\nu, s) = C_2(s) \sin(\alpha_0 \nu) - \frac{C_1(s)}{2R} \nu \sin(\alpha_0 \nu) + \frac{3C_0(s)}{8R^2} \nu^2 \sin(\alpha_0 \nu).
\]

(3.17)

Equation (3.16) is a Hill’s equation which has periodic solutions for an infinite countable sequence of the parameter \( \alpha_2 \) [3]. We can observe that \( C_0 \) depends on two independent fundamental solutions of (3.16).

So, we obtain the leading term \( w_0 \) of the longitudinal field and the approximation of the dispersion relation:

\[
\omega^2 \varepsilon \mu = \beta^2 + \eta^{-2}l^{-2} \alpha_0^2 + 2l^{-2} \alpha_0 \alpha_2 + O(\eta).
\]

(3.18)

As for the transversal electric field, from \( h_3 = 0 \) and equation (2.2-2), we get \( \text{rot rot } e = 0 \). Thus, from (2.7), we have approximation of \( e \) on the local basis. We introduce the decomposition on the local basis:

\[
e = u\vec{n} + v\vec{\tau}.
\]

</tbody>
</table>

The leading term of each component is (with the similar notations as in (3.6-1)):

\[ u_1(\nu, s) = -\beta l_0^{-1} C_0(s) \cos(\alpha_0 \nu), \quad v_2(\nu, s) = -\beta l_0^{-2} C'_0(s) \sin(\alpha_0 \nu). \]

We observe therefore that, in this case, the longitudinal component is the significant term.

For a circular section, the characteristic length of \( \Gamma_0 \) is the radius, \( R = 1 \), and an approximation of \( \sqrt{\omega^2 \varepsilon - \beta^2} \) is:

\[ \eta^{-1} \alpha_{\text{app}} = \eta^{-1} n \pi + \frac{\eta}{2n\pi} \left( m^2 - \frac{1}{4} \right) (n \in \mathbb{N}^*, \ m \in \mathbb{N}) . \]

Some computed values \( \eta^{-1} \alpha \) and \( \eta^{-1} \alpha_{\text{fem}} \) are compared to \( \eta^{-1} \alpha_{\text{app}} \), for \( \eta = 0.05 \) (Tab. 1). The value \( \eta^{-1} \alpha \) is obtained from the use of Mathematica® and \( \eta^{-1} \alpha_{\text{fem}} \) from a finite elements method (code ASTER for a quarter circle with 32 841 nodes in the radial direction, with linear element approximation). The parameter \( m \) is related to the index of Bessel’s functions.

For \( m \neq 0 \), we observe that the order of multiplicity of the eigenvalues \( \eta^{-1} \alpha_{\text{fem}} \) is 2.

The difference between the \( \text{fem} \) solution and the approximation comes from the error of finite elements approximation. It should be reduced by increasing the number of nodes.

3.3. Transverse electric (TE) wave: \( b_3 \neq 0, \ e_3 = 0 \)

In this case, from equation (2.7), we have \( \text{div} \epsilon = 0 \) and the Hodge’s decomposition [1] of \( \epsilon \) is: \( e_1 = p_2, \ e_2 = -p_1, \) i.e. \( \epsilon = \text{grad} p \wedge \vec{x}_3 \). The unknown scalar function \( p \) can be determined from the Neumann problem:

\[
\begin{align*}
\Delta p + (\omega^2 \varepsilon \mu - \beta^2) p &= 0 & \text{in} & \quad \Omega \\
\frac{\partial p}{\partial n} &= 0 & \text{on} & \quad \partial \Omega.
\end{align*}
\]

(3.20) (3.21)

For small values of the parameter \( \eta \), in a similar way as for the TM wave, we search expansions for a solution of this eigenvalue problem:

\[
p = p_0 + \eta p_1 + \eta^2 p_2 + \ldots; \quad \eta^l \sqrt{\omega^2 \varepsilon \mu - \beta^2} = a_0 = a_0 + \eta a_1 + \eta^2 a_2 + \ldots
\]

(3.22)

We insert these expressions in (3.20), (3.21) and, using (3.3-2), we identify powers of \( \eta \). Various problems are obtained whose equations are similar to the preceding ones, (3.7), (3.10), (3.14), with \( a_i \) instead of \( \alpha_i \), \( (i = 0, 1, 2 \ldots) \). The boundary conditions are different: \( \frac{\partial p_0}{\partial n} = 0 \).

At order \( \eta^0 \), a first case emerges:

\[
a_0 = 0.
\]

(3.23)

The first approximation of \( p \) is: \( p_0(\nu, s) = D_0(s) \). At order \( \eta \), we get: \( p_1(\nu, s) = D_1(s) \). The term \( \eta^2 \) (see (3.14)) provides to the function \( D_0 \). As to respect the periodicity, if \( T \) denotes the non dimensional length of the curve \( \Gamma_0 \), we obtain:

\[
a_1 = 2\pi m/T \quad (m \in \mathbb{N}^*); \quad D_0(s) = A_0 \cos(a_1 s) + B_0 \sin(a_1 s).
\]

(3.24)

</tbody>
</table>

$A_0$ and $B_0$ are arbitrary constants. An approximation of the solution of the problem is then, using (3.3.1) and the notation (3.19):

$$\omega^2 \varepsilon \mu = \beta^2 + l^{-2}a_1^2 + O(\eta); \quad u_0(\nu, s) = 0, \quad v_0(\nu, s) = l^{-1}a_1[-A_0 \sin(a_1s) + B_0 \cos(a_1s)].$$

(3.25)

In the general case ($a_0 \neq 0$), at order $\eta^0$, we obtain:

$$a_0 = a_0(n) = n\pi \ (n \in \mathbb{N}^*); \quad p_0(\nu, s) = D_0(s) \cos(a_0\nu).$$

(3.26)

We use the same step as in Section 3.2. At order $\eta$, after a projection on $\cos(a_0\nu)$, we obtain $a_1$ and then the function $p_1$.

$$a_1 = 0; \quad p_1(\nu, s) = D_1(s) \cos(a_0\nu) + \frac{D_0(s)}{2a_0^2R} [\sin(a_0\nu) - \nu a_0 \cos(a_0\nu)].$$

(3.27)

At order $\eta^2$, the following Hill’s equation supplies the term $a_2$ and the function $D_0(s)$:

$$\frac{d^2D_0}{ds^2} + \left( 2a_0a_2 - \frac{3}{4R^2} \right) D_0 = 0.$$ 

(3.28)

The transversal electric field is deduced from $p$, and the leading term of each component on the local basis is, for $a_0 \neq 0$:

$$u_1(\nu, s) = l^{-1} D_0(s) \cos(a_0\nu); \quad v_0(\nu, s) = l^{-1} D_0(s) a_0 \sin(a_0\nu).$$

(3.29)

The tangential component here is the significant term. An approximation of the dispersion relation is, in this case:

$$\omega^2 \varepsilon \mu = \beta^2 + \eta^{-2}l^{-2} a_0^2 + 2l^{-2} a_0 a_2 + O(\eta).$$

(3.30)

For a circular section, with $R = 1$, some computed values $\eta^{-1}a$, $\eta^{-1}a_{\text{fem}}$, and approximations $\eta^{-1}a_{\text{app}}$, $\eta^{-1}a_{\text{app}} = \eta^{-1}n\pi + \frac{2}{3} \left( m^2 + \frac{1}{4} \right) \ (n \in \mathbb{N}^*, m \in \mathbb{N})$, are compared for $\eta = 0.05$ (Tab. 2).

A good agreement between these some values $\eta^{-1}a$ and $\eta^{-1}a_{\text{app}}$ is observed.

3.4. Transverse electric magnetic (TEM) wave: $e_3 = 0, h_3 = 0$

From $h_3 = 0$ and (2.2-2), we have $\text{rot} \text{rot} e = 0$. So, from $e_3 = 0$ and (2.7), we get the well known result: $\omega^2 \varepsilon \mu = \beta^2$. The relation between the frequency and the wave number does not depend on the geometry of the section.

As for the electric field, it is given, as in Section 3.3, from a scalar function $p$ which satisfies:

$$\Delta p = 0 \quad \text{in} \quad \Omega$$

(3.31)

$$\frac{\partial p}{\partial n} = 0 \quad \text{on} \quad \partial\Omega.$$ 

(3.32)

We identify the successive powers of $\eta$ in the expansions of (3.31) and (3.32). An approximation of $p$ is $p_0(\nu, s) = D_0s + E_0, (D_0, E_0 \text{ constant})$. And the leading term of $e$ is $u_0\tilde{n}$, with $u_0 \text{ constant}$.

We can mention that, for TM and TE waves, the first approximation of $\omega^2 \varepsilon \mu - \beta^2$ is the same.
4. Justification of the approximations

Let us consider a TM wave. The justification of the results of Section 3.2 comes from a variational form $P_\eta$ of the eigenvalue problem (2.5), (2.6) for the longitudinal electric field. We introduce a test function $\varphi$ of the Sobolev space $H^1_0(\Omega)$. Owing to a Green’s formula, we obtain:

$$w_\eta \in H^1_0(\Omega); \quad \int_\Omega \text{grad} w_\eta \cdot \text{grad} \varphi \, dx = (\omega^2 \varepsilon \mu - \beta^2) \int_\Omega w_\eta \varphi \, dx, \quad \forall \varphi \in H^1_0(\Omega).$$

In the variables $(\eta, s)$, the problem $P_\eta$ follows:

$$w_\eta \in H^1_0(\Omega); \quad a_\eta(w_\eta, \varphi) = a_\eta^2 b_\eta(w_\eta, \varphi), \quad \forall \varphi \in H^1_0(\Omega) \quad (4.1)$$

where $a_\eta$ et $b_\eta$ are the bilinear forms

$$a_\eta(w, \varphi) = \int_\Omega \left( \frac{\partial w}{\partial \nu} \frac{\partial \varphi}{\partial \nu} + \frac{\eta^2}{\sigma^2} \frac{\partial w}{\partial s} \frac{\partial \varphi}{\partial s} \right) \sigma \, d\nu ds, \quad b_\eta(w, \varphi) = \int_\Omega w \varphi \sigma \, d\nu ds.$$

As $\Omega$ can be identified, in the variables $(\eta, s)$, to the set $[0, 1] \times [0, T]$ ($T$ is the non dimensional length of the interior closed curve $\Gamma_0$), the accurate meaning of $\varphi \in H^1_0(\Omega)$ is that $\varphi$ belongs to the Sobolev space $H^1([0, 1] \times [0, T])$ and satisfies:

$$\varphi(0, s) = \varphi(1, s) = 0, \quad \varphi(\nu, 0) = \varphi(\nu, T). \quad (4.2)$$

In other words, the test function is an element of $H^1_{0,p}([0, 1] \times [0, T])$ ($0$ for the boundary conditions on $\eta, p$ for the periodicity on $s$).

According to the results of Section 3.2, we define new eigenfunction and test function: $w_\eta(\nu, s) = \sigma^{-\frac{1}{2}} f_\eta(\nu, s)$, $\varphi(\nu, s) = \sigma^{-\frac{1}{2}} \psi(\nu, s)$, with $a = 1 + \eta \nu R^{-1}$.

We obtain for $P_\eta$:

$$f_\eta \in H^1_{0,p}([0, 1] \times [0, T]); \quad \int_0^1 \int_0^T \left[ \frac{\partial f_\eta}{\partial \nu} \frac{\partial \psi}{\partial \nu} + \frac{\eta^2}{\sigma^2} \frac{\partial f_\eta}{\partial s} \frac{\partial \psi}{\partial s} \right] \sigma \, d\nu ds = \alpha_0^2 \int_0^1 \int_0^T f_\eta \psi \, d\nu ds, \quad \forall \psi \in H^1_{0,p}([0, 1] \times [0, T]).$$

Let us pay attention to the first terms of the integral in the first member and, specially, to the second one. Using an expansion of the expression (3.2-2) of $\sigma$, we transform it. After integrations by parts and thanks to (4.2-1), we obtain that problem $P_\eta$ appears to be a perturbation of the eigenproblem:

$$\tilde{w}_\eta \in H^1_{0,p}([0, 1] \times [0, T]); \quad \int_0^1 \int_0^T \left[ \frac{\partial \tilde{w}_\eta}{\partial \nu} \frac{\partial \psi}{\partial \nu} + \gamma \frac{\partial \tilde{w}_\eta}{\partial s} \frac{\partial \psi}{\partial s} - \frac{\eta^2}{R^2} \tilde{w}_\eta \psi \right] \, d\nu ds = \gamma^2 \int_0^1 \int_0^T \tilde{w}_\eta \psi \, d\nu ds, \quad \forall \psi \in H^1_{0,p}([0, 1] \times [0, T]).$$

We can verify that the function $\tilde{w}_\eta(\nu, s) = C_0(s) \sin(\alpha_0 \nu)$, with $C_0$ being a T-periodic solution of (3.16), is an eigenfunction of this problem, associated to the eigenvalue $\alpha_0^2 + 2\eta^2 \alpha_0 \alpha_2$. And Kato’s perturbation theorem [4] gives a justification of the approximations of Section 3.2.
We can present here a variational form of the eigenvalue problem issued from the Hill’s equation (3.16).

Denoting by $H^1_p[0,T]$ the set of the $T$-periodic elements of $H^1[0,T]$, we have:

$$C_0 \in H^1_p[0,T]; \quad \int_0^T \left( \frac{dC_0}{ds} d\nu - \frac{1}{4R^2} C_0 \right) ds = 2\alpha_0 \alpha_2 \int_0^T C_0 c ds, \quad \forall c \in H^1_p[0,T]. \quad (4.3)$$

As the boundary is regular, $R(s)$ is continuous on the interval $[0,T]$. After the shift of the spectral parameter: $2\alpha_0 \alpha_2 \rightarrow 2\alpha_0 \alpha_2 + m^2$, $m^2 = \max (1/R^2(s))$ for $s \in [0,T]$, we obtain a standard eigenvalue problem on $H^1_p[0,T]$, from which computational values of $C_0$ and $\alpha_2$ can be derived.

For the TE wave, the same approach leads to the justification.

5. APPROXIMATIONS FOR A PIECEWISE $C^1$ BOUNDARY

5.1. Equations near a corner

The presence of an angular point has two effects. First, it involves a modification in the preceding approximations. And, in addition, it introduces other modes, we can call them “corner modes”.

The TM wave problem is considered. Our study is mainly devoted to the perturbation brought by a corner, in the previous results. Let $O$ be an angular point of $\Gamma_0$. Near $O$ three regions are to be considered (Fig. 3).

![Figure 3. The geometry near a corner.](image)

$\Omega^{(1)}$ and $\Omega^{(3)}$ are strips with thickness $\eta l$. We assume that in $\Omega^{(1)}$, $s \leq T$ and in $\Omega^{(3)}$, $s \geq 0$. $\Omega^{(2)}$ is a curvilinear quadrilateral $OACB$, with an angle $\phi$ in $O$. The geometry of this quadrilateral should be specified but it does not interfere in the first approximation of the field.

For the study in $\Omega^{(2)}$, a suitable local basis is $(\overrightarrow{OA}, \overrightarrow{OB})$ with $\overrightarrow{OA} = \eta l \overrightarrow{n}(T^-)$ and $\overrightarrow{OB} = \eta l \overrightarrow{n}(0^+)$. A point $P$ in $\Omega^{(2)}$ is located by: $\overrightarrow{OP} = x\eta l \overrightarrow{n}(T^-) + y\eta l \overrightarrow{n}(0^+)$. We consider the case of only one angular point, so $\Omega^{(1)} = \Omega^{(3)}$. In $\Omega^{(1)}$, the field $w^{(1)}_\eta(\nu, s)$ satisfies the equation and boundary conditions:

$$\frac{\partial^2 w^{(1)}_\eta}{\partial \nu^2} + \frac{\eta}{\sigma R} \frac{\partial w^{(1)}_\eta}{\partial \nu} + \frac{\eta^2}{\sigma^2} \frac{\partial^2 w^{(1)}_\eta}{\partial s^2} + \frac{\nu R'}{\sigma^3 R^2} \frac{\partial w^{(1)}_\eta}{\partial \nu} + \alpha^2 w^{(1)}_\eta = 0 \quad (5.1)$$

$$w^{(1)}_\eta(0, s) = w^{(1)}_\eta(1, s) = 0. \quad (5.2)$$

In $\Omega^{(2)}$, the field $w^{(2)}_\eta(x, y)$ satisfies the equation and boundary conditions:

$$\frac{\partial^2 w^{(2)}_\eta}{\partial x^2} + \frac{\partial^2 w^{(2)}_\eta}{\partial y^2} + \alpha^2 w^{(2)}_\eta = 0 \quad (5.3)$$

$$w^{(2)}_\eta = 0 \quad \text{on } A\overline{C} \text{ and } B\overline{C}. \quad (5.4)$$
These problems are to be completed by conditions of continuity on \( O\tilde{A} \) and \( O\tilde{B} \). On \( O\tilde{A} \), using (3.3-1), we have:
\[
w(1)(\nu, T) = w(2)(\nu, T) = \frac{\eta}{\sigma(T)} \frac{\partial w(1)}{\partial s}(\nu, T) = -\frac{\partial w(2)}{\partial n}(x, 0), \quad \text{for} \quad 0 \leq \nu = x \leq 1 
\]
with \( \frac{\partial w(2)}{\partial n}(x, 0) = \cot \alpha \frac{\partial w(2)}{\partial x}(x, 0) - (\sin \alpha)^{-1} \frac{\partial w(2)}{\partial y}(x, 0) \). Similar conditions exist on \( O\tilde{B} \).

We assume expansions of the eigenelements, similar to (3.6). We study how the presence of the angular point modifies the first approximation, i.e. the terms \( w(1)_0 \) and \( \alpha_2 \).

5.2. First approximation

As no transversal boundary conditions is prescribed in the problem (5.1), (5.2), in \( \Omega^{(1)} \) some results obtained section 3 still remain, and specially:
\[
\alpha_0 = \alpha_0(n) = n\pi, \quad \alpha_1 = 0, \quad w(1)_0(\nu, s) = C(1)_0(s) \sin(\alpha_0\nu).
\]
The problem in \( \Omega^{(2)} \), at order \( \eta^0 \), is a homogeneous problem, with Dirichlet-Neumann conditions deduced from (5.4) and (5.5-2). It has only one solution: \( w(2)_0(x, y) = 0 \), except for special cases we do not study. According to the continuity of the field on \( OA \) and \( OB \), we obtain:
\[
C(1)_0(T) = C(1)_0(0) = 0. 
\]
So, a restriction has to be done among the previous solutions of the Hill’s equation (3.16). From this supplementary condition, we can remark that \( C(1)_0(s) \) is generated by only one fundamental solution of (3.16).

Such result is valid for more than one angular point. But, for special geometries, indeterminations can occur and to go on the next terms, we have to deal with stiff problems. Both conditions of continuity on \( OA \cup OB \) cannot be satisfied locally. For one of them, we adopt a global condition. An example is given in Section 6.

To justify the first approximation, we can use the arguments developed in [5] (Chap. VII). We transform the problem in one settled on \( \Omega^{(1)} \), thank to a frontier operator defined from the problem in \( \Omega^{(2)} \). The problem obtained is in the general framework of holomorphic perturbation theory.

5.3. Corner modes

Another kind of waves which can propagate is those due mainly to the angular point. In this case, the field is prevalent in the corner. But, in general, the eigenvalue is different from \( n\pi \), so elsewhere than in the corner, the field is null. Another partition of the domain \( \Omega \) is made, insulating the corner (Fig. 4).

![Figure 4. Geometry for the corner modes.](image)

In such a geometry, the singularity that can occur in \( O \) can be taken in account.

The continuity of the field implies that \( \alpha \) is an eigenvalue of the Dirichlet problem in \( \Omega^{(2)} \):
\[
\frac{\partial^2 w(2)}{\partial x^2} + \frac{\partial^2 w(2)}{\partial x^2} + \alpha^2 w(2) = 0 \quad \text{in} \quad \Omega^{(2)} \\
w(2) = 0 \quad \text{on} \quad \partial\Omega^{(2)}. 
\]

Of course, the approximation which is obtained depends on the choice of the domain \( \Omega^{(2)} \). A study would be done to optimise the results.
6. THIN SQUARE WAVEGUIDER

6.1. Analytical results

To illustrate the case of more than one angular point, we present explicit expressions of approximations for
the TM waves in a thin square guide. Thanks to the symmetries of the section, we can reduce the domain.
Also, we get simplifications in the equations, coming from the fact that the curvature is null in every smooth
point of $\Gamma_0$.

The section has a centre and three independent axis of symmetry: two are parallel to the sides of the interior
square and the other has the direction of one of the bisecting lines. So the domain can be reduced to the eighth
of the section. Figure 5 shows the general shape of the selected eighth of the section and the exact shape in
variables $(\nu, s)$ and $(x, y)$.

The domain is divided in $\Omega(1)$, part of the side, $\Omega(1) = \{(\nu, s), 0 \leq \nu \leq 1, -1/2 \leq s \leq 0\}$ and in $\Omega(2)$, part
of the corner, $\Omega(2) = \{(x, y), 0 \leq x \leq 1, 0 \leq y \leq 1, x \leq y\}$ (in the non dimensional variables).

The boundary conditions on the sides $[CD]$ and $[OA]$ depend on the properties of the field. On an axis of
symmetry, the condition to be taken is:

$$\frac{\partial w}{\partial n} = 0 \text{ for a symmetrical field; } w = 0 \text{ for an antisymmetrical field.}$$

a) Case of a symmetrical field compared to the lines $[CD]$ and $[OA]$.

Taking into account simplifications, the equations of the problem are:

In $\Omega(1)$

$$\frac{\partial^2 w^{(1)}}{\partial \nu^2} + \eta^2 \frac{\partial^2 w^{(1)}}{\partial s^2} + \alpha_\eta^2 w^{(1)} = 0 \quad (6.1)$$

$$w^{(1)}(\nu, 0) = w^{(1)}(1, s); \quad \frac{\partial w^{(1)}}{\partial s}(\nu, -\frac{1}{2}) = 0. \quad (6.2)$$

In $\Omega(2)$

$$\frac{\partial^2 w^{(2)}}{\partial x^2} + \frac{\partial^2 w^{(2)}}{\partial y^2} + \alpha_\eta^2 w^{(2)} = 0 \quad (6.3)$$

$$w^{(2)}(x, 1) = 0; \quad \frac{\partial w^{(2)}}{\partial n}(x, x) = 0. \quad (6.4)$$

To these equations, we have to add the conditions of continuity on $[OB]$:

$$w^{(1)}(\nu, 0) = w^{(2)}(0, y); \quad \eta \frac{\partial w^{(1)}}{\partial s}(\nu, 0) = \frac{\partial w^{(2)}}{\partial x}(0, y) \quad (\nu = y). \quad (6.5)$$
For $\eta \ll 1$, the results obtained in Section 3 are valid and they provide general expressions of the different terms of the approximations. In $\Omega^{(1)}$, from (6.1) and (6.2-1), we get:

\[ w_j^{(1)}(\nu, s) = C_j^{(1)}(s) \sin(n\pi \nu) \quad (j = 0, 1, 2, ...); \quad \alpha_0 = n \pi, \quad \alpha_1 = 0 \]  
\[ \frac{d^2 C_0^{(1)}}{ds^2} + 2\alpha_0 \alpha_2 C_0^{(1)} = 0 \quad \left(0 < s < \frac{1}{2}\right). \]  
\[ (6.6) \]
\[ (6.7) \]

And from (6.2-2), we have the condition:

\[ \frac{dC_j^{(1)}}{ds} \left(-\frac{1}{2}\right) = 0 \quad (j = 0, 1, 2). \]  
\[ (6.8) \]

This relation provides one of the boundary condition for equation (6.7), the other comes from the solution in $\Omega^{(2)}$ and the continuity on $[OB]$. For the problem in $\Omega^{(2)}$, we have to deal with two conditions on $[OB]$, for $j = 0, 1, 2$ and $\nu = y$:

\[ w_j^{(2)}(0, y) = C_j^{(1)}(0) \sin(n\pi \nu); \quad \frac{\partial w_j^{(2)}}{\partial x}(0, y) = 0, \quad \frac{\partial w_{j+1}^{(2)}}{\partial x}(0, y) = \frac{dC_j^{(1)}}{ds}(0) \sin(n\pi \nu). \]  
\[ (6.9) \]

Both cannot be satisfied locally. We use global properties and from a variational form of the problem we determine relations between the unknown coefficients $C_j^{(1)}(0)$.

Let us consider the function: $\varphi_n(x, y) = (1 - y)\sin(n\pi x) + (1 - x)\sin(n\pi y)$. It satisfies equation (6.3), with $\alpha_2^2 = n^2\pi^2$, and the boundary conditions (6.4). Thanks to a Green’s formula, from (6.3), (6.4) and (6.5), we obtain:

\[ \int_0^1 \eta \frac{\partial w_0^{(1)}}{\partial s}(y, 0) \sin(n\pi y) - w_0^{(1)}(y, 0) [n\pi (1 - y) - \sin(n\pi y)]dy = (\alpha_2^2 - n^2\pi^2) \int_{\Omega^{(2)}} w_0^{(2)} \varphi_n \, dx \, dy. \]  
\[ (6.10) \]

The identification in (6.10) of the successive terms, powers of $\eta$, provides relations between the coefficients $C_j^{(1)}(0)$.

At order $\eta^0$, we get, in agreement with Section 5: $C_0^{(1)}(0) = 0$. So, the function $C_0^{(1)}(s)$ satisfies (6.7) and:

\[ \frac{dC_0^{(1)}}{ds} \left(-\frac{1}{2}\right) = 0, \quad C_0^{(1)}(0) = 0. \]  
\[ (6.11) \]

The solution of this differential problem gives the approximations:

\[ 2\alpha_0 \alpha_2 = (2p + 1)^2\pi^2 \quad (p \in \mathbb{N}); \quad C_0^{(1)}(s) = A_0^{(1)} \sin[(2p + 1)\pi s]. \]  
\[ (6.12) \]

As for the field $w_0^{(2)}$, it satisfies:

\[ \frac{\partial^2 w_0^{(2)}}{\partial x^2} + \frac{\partial^2 w_0^{(2)}}{\partial y^2} + \alpha_2^2 w_0^{(2)} = 0 \]  
\[ (6.13) \]
\[ w_0^{(2)}(0, y) = 0, \quad \frac{\partial w_0^{(2)}}{\partial x}(0, y) = 0 \]  
\[ (6.14) \]
\[ w_0^{(2)}(x, 1) = 0, \quad \frac{\partial w_0^{(2)}}{\partial n}(x, x) = 0. \]  
\[ (6.15) \]
Let us consider the problem (6.13), (6.14-1) and (6.15). Its solution depends on the eigenvalues of the associated eigenvalue problem. These eigenvalues and eigenfunctions are:

\[ \omega_{q,r}^2 = \pi^2(q^2 + r^2) \quad (q, r \in \mathbb{N}^*), \quad w_{q,r}(x,y) = \sin(q\pi x) \sin(r\pi y) + \sin(q\pi y) \sin(r\pi x). \] (6.16)

- For \( n^2 \neq q^2 + r^2 \), i.e., when \((q, r, n)\) is not a pythagorician triplet, the only solution of (6.13), (6.14-1) and (6.15) is \( w_0^{(2)}(x,y) = 0 \). This function which also satisfies (6.14-2) is the solution of (6.13), (6.14) and (6.15). In this case, we get the following approximations of the eigenvalue and the normalized eigenfunction (in \( L^2([0,1] \times [-1/2,0]) \)):

\[ \alpha_\text{app} = n \pi + \eta^2 \frac{(2p+1)^2}{2n} \pi + O(\eta^3) \quad (n \in \mathbb{N}^*, \ p \in \mathbb{N}) \] (6.17)

\[ w_0^{(1)}(\nu,s) = 2\sqrt{2}\sin(n\pi\nu) \sin[(2p+1)\pi s], \quad w_0^{(2)}(x,y) = 0. \] (6.18)

These approximations are periodic and depend on two integers.

At order \( \eta^1 \), (6.10) involves that, for \( s = 0 \), \( C_1^{(1)} \) and \( dC_0^{(1)}/ds \) are equal and we get:

\[ C_1^{(1)}(0) = 2\sqrt{2}(2p+1)\pi. \] (6.19)

We can specify the function \( C_1^{(1)}(s) \) if we continue the research of the approximations in \( \Omega^{(1)} \). From the term \( \eta^3 \) in (6.1), we obtain, after a projection on \( \sin(n\pi\nu) \) as in Section 3:

\[ \frac{d^2C_1^{(1)}}{ds^2} + 2\alpha_0\alpha_2 C_1^{(1)} = -2\alpha_0\alpha_3 C_0^{(1)}. \] (6.20)

The solution of (6.20), (6.8) is, with (6.19):

\[ \alpha_3 = 4\alpha_2; \quad C_1^{(1)}(s) = A_1^{(1)} \sin[(2p+1)\pi s] + C_1^{(1)}(0)(1+2s) \cos[(2p+1)\pi s]. \] (6.21)

The constant \( A_1^{(1)} \) is determined from the normalization of the eigenfunction, what amounts choosing \( w_1^{(1)} \) orthogonal to \( w_0^{(1)} \). We choose \( A_1^{(1)} = 2\sqrt{2} \).

To exhibit an explicit approximation of \( w_1^{(2)} \), we make the assumption that (6.9-1) is satisfied, whereas (6.9-2) is globally satisfied thanks to the fundamental relation (6.10). And we have:

\[ w_1^{(2)}(x,y) = C_1^{(1)}(0)[(1-y) \sin(n\pi x) + (1-x) \sin(n\pi y)]. \] (6.22)

The next approximation can be obtained in a similar way.

- For \( n^2 = q^2 + r^2 \), \( w_0^{(2)} \) is one of the eigenfunction \( k_0 w_{q,r} \) of (6.16) \((k_0 \) constant). We choose \( w_{q,r} \) for test function in a variational form of the problem in \( \Omega^{(2)} \). From the structure (6.6-1) of the solution in \( \Omega^{(1)} \), we obtain that \( w_0^{(2)} \) is orthogonal to \( w_{q,r} \). So \( w_0^{(2)} = 0 \) and the previous approximations are still valid.

b) Case of a symmetrical field compared to (CD) and antisymmetrical compared to (OA)

For the problem in \( \Omega^{(2)} \), to the condition (6.4-2) we have to substitute: \( w_0^{(2)}(x,x) = 0 \).

With a method similar to that of a), we consider here the test function: \( \psi_0(x,y) = -(1-y)\sin(n\pi x) + (1-x)\sin(n\pi y) \). We obtain that the approximations (6.17), (6.18) and (6.21-2) are still valid. But \( C_1^{(1)}(0) \) and \( \alpha_3 \) are different:

\[ C_1^{(1)}(0) = -\frac{2}{3}\sqrt{2}(2p+1)\pi; \quad \alpha_3 = -\frac{4}{3}\alpha_2. \]

Table 3 shows the agreement of these results with the computations.
Table 3. Approximations and computed eigenvalues.

Figure 6. Corner mode $\eta^{-1}\alpha_{fem} = 59.60$.

Figure 7. Symmetrical field / (CD) ($n = 1, m = 3$), antisymmetrical field / (OA) $\eta^{-1}\alpha_{fem}^{(a)} = 63.52$.

c) Case of an antisymmetrical field compared to the lines (CD) and (OA)

The boundary conditions along these lines are now respectively:

\[ w^{(1)}_\eta \left( \nu, -\frac{1}{2} \right) = 0; \quad w^{(2)}_\eta (x, x) = 0. \]

In the same way as previously, we obtain the system for the determination of $C^{(1)}_0(s)$:

\[ \frac{d^2 C^{(1)}_0}{ds^2} + 2\alpha_0\alpha_2 C^{(1)}_0 = 0 \quad \left( 0 < s < \frac{1}{2} \right); \quad C^{(1)}_0 \left( -\frac{1}{2} \right) = 0, \quad C^{(1)}_0 (0) = 0. \]

So, an approximation of the eigenelements is:

\[ \alpha_{app} = n \pi + \eta^2 \frac{(2p)^2}{2n} \pi + O(\eta^3) \quad (n \in \mathbb{N}^*, p \in \mathbb{N}^*) \quad (6.23) \]

\[ w^{(1)}_0 (\nu, s) = 2\sqrt{2} \sin(n\pi\nu) \sin(2p\pi s), \quad w^{(2)}_0 (x, y) = 0. \quad (6.24) \]

These results (6.23) and (6.24) still hold true in the case of an antisymmetrical field compared to (CD) and symmetrical to (OA).
To summarize, the first approximation which is found for a TM wave is:

\[ \eta^{-1} \alpha_{\text{app}} = \frac{n\pi}{\eta} + \frac{m^2 \pi}{2n} \quad (n \in \mathbb{N}^*, m \in \mathbb{N}^*) \]  

(6.25)

\[ w_0^{(1)}(\nu, s) = 2\sqrt{2} \sin(n\pi \nu) \sin(m\pi s), \quad w_0^{(2)}(x, y) = 0. \]  

(6.26)

6.2. Comparison with computed results

Table 3 shows results which are obtained, with \( \eta = 0.05 \), for fields which propagate in the sides of the section. \( \eta^{-1} \alpha_{\text{app}} \) denotes the analytical approximation (6.25) and \( \eta^{-1} \alpha_{\text{fem}} \) is the value obtained from a finite elements method (code ASTER, 67281 nodes, with linear finite elements approximation, for a quarter of the section). The two values \( \eta^{-1} \alpha_{\text{fem}}^{(a)}, \eta^{-1} \alpha_{\text{fem}}^{(s)} \) are respectively related to antisymmetrical and symmetrical modes in the corners, i.e. along \((OA)\).

The finite elements method also provide the corner modes (Fig. 6). The first eigenvalue of these modes is lower than all the preceding ones: \( \eta^{-1} \alpha_{\text{fem}} = 59.603 \).

A visualisation of other modes shows the agreement with the expression (6.26), both for symmetrical modes (Fig. 7) and for antisymmetrical ones (Figs. 8 and 9).

One can observe that the values are close, the difference between them being less than 1%. The asymptotic approximations seem to be less expensive. They provide values which are obtained by finite elements method with fine meshes. Moreover, the asymptotic method proposes continuous expression of the field.
