TWO APPROACHES TO COMPUTE UNSTEADY COMPRESSIBLE TWO-PHASE FLOW MODELS WITH STIFF RELAXATION TERMS

JEAN-MARC HÉRARD$^{1,2,*}$ AND GUILLAUME JOMÉE$^{1,2}$

Abstract. The paper deals with the numerical modeling of two-phase flows while using Baer–Nunziato type models. Focus is given here on the numerical treatment of source terms that involve three (or four) relaxation time scales. A new coupled approach relying on the continuous analysis of the system of ODEs is compared with a more widely used strategy grounded on the fractional step approach. Properties of schemes are given in both cases. Several numerical applications show that the coupled approach should be preferred for both stability and accuracy reasons.

Received September 14, 2022. Accepted November 6, 2023.

1. Introduction

Many industrial studies urge the development of suitable models and reliable numerical tools, in order to predict two-phase or even multiphase flows. While restricting to two-phase flows, at least two different modelling strategies may be considered.

A first one basically assumes that inner processes involving various relaxation time scales are such that a full instantaneous equilibrium is reached everywhere in the flow. This has led to a rather broad class of so-called homogeneous two-phase flow models, among which we may at least cite [1, 4, 22, 39, 47].

When very fast transients are at stake or when droplet atomization occurs, a second strategy, which is grounded on full disequilibrium models, may be retained. The present contribution clearly lies within this framework. More precisely, focus will be given on a class of two-phase flow models that is now well-known, see [3, 13, 14, 25, 29, 30, 32, 38, 48, 55, 60] among others. It must be recalled that three (respectively four) relaxation time scales are embedded in these gas–liquid (respectively liquid–vapour, thus including mass transfer) flow models. The latter time scales obviously require suitable closure laws, that can be found in the literature, see [4, 7, 8, 19, 28, 46, 54] among others. These relaxation time scales may be quite distinct and may depend on the application. Assumptions regarding some relaxation time scales may lead to relaxation models such as [23, 24, 34, 51] among others. In the present work, no hypothesis concerning the relaxation time scales is retained, in order to preserve the widest range of applications.

Keywords and phrases. Two-phase flows, entropy, finite volumes, relaxation process, jump conditions.

Moreover, the dynamics of the underlying relaxation process in Baer–Nunziato type models has not been thoroughly studied yet. This question is often (implicitly) addressed by seeing the total entropy as a Lyapunov function. In the homogeneous case, i.e. without convective terms, that ensures the stability close to the steady state, or equivalently here, close to the mechanical and thermodynamic equilibrium between the two-phases. However, in many cases, such as vapour explosion or loss-of-coolant accidents, the initial conditions may be set far from thermodynamic equilibrium. Thus, a better understanding of the effective relaxation process is crucial, in order to guarantee the return to equilibrium. In this paper, conditions of effective relaxation are exhibited and discussed for various equations of state (EOS).

Up to now, most of the numerical strategies that have been proposed in order to obtain approximate solutions of these non-equilibrium two-phase flow models, are grounded on the use of a two-step algorithm. The latter includes:

(i) an explicit evolution step that treats all convective contributions together with help of Riemann solvers, relaxation solvers or Discontinuous Galerkin methods, see for example [2,14,16,17,25,35,55,58,59,61,63,64], and

(ii) an implicit step that deals with source terms associated with the former relaxation time scales, as in [2,17,18,25,26,35,52,53,55,58] among others.

It seems worth emphasizing that, in the framework of immiscible three-phase flow models, such as those proposed in [40], the problem of the preservation of admissible states through the convective subsystem (step (i)) has been addressed in Section 2.2.4 of [6], while focusing on simple Stiffened Gas EOS. This result obviously applies in the framework of two-phase flow models considered here. The first explicit step (i) introduces some constraint on the time step for obvious stability issues. This, in turn, renders the implicit treatment of step (ii) mandatory.

Concerning the second implicit step (ii), a fractional step approach has been widely applied up to now, that treats separately the distinct relaxation time scales, see [2,17,18,26,35,55] among others. In addition, the numerical treatment of the source terms, using strong hypothesis on some relaxation time scales, has been investigated in the literature, see for example [36,52,53]. However, the fractional step approach used for handling the source terms may suffer from deficiencies, and even lead to a blow-up of the code in some extreme situations, see for example [6] which tackles the problem of vapour explosion. Hence, this motivates to investigate further on the set of coupled ODEs accounting for source terms, and meanwhile derive relevant and more coupled schemes in order to tackle extreme situations. In the present work, a new robust numerical scheme without any assumption on the relaxation time scales is presented.

In the following, emphasis is given on the stability of the scheme. We will also examine whether the accuracy of the new scheme is improved, or not, on a given mesh size, by comparing it with the fractional step approach.

The paper is organised as follows. The governing set of equations is recalled first, and the main properties of the model are given. A few results are then provided and discussed, which concern the true inner relaxation process with respect to temperature, pressure, and velocity in gas–liquid flow models. Afterwards, two distinct algorithms will be considered. The first one is classical. It takes the three (respectively four) relaxation effects into account in a fractional step approach involving three steps when dealing with gas–liquid flows (respectively four in the case of liquid–vapour flows). The second one relies on the investigation of coupled relaxation effects, as discussed in Section 2. Some important properties of the latter schemes are detailed. Both schemes are tested against Chauvin experiment, and a more complex situation arising from the vapour explosion framework. As expected, the comparison of the two schemes is clearly in favour of the coupled algorithm. Appendices complete the paper. In particular, Appendix G discusses the influence of the ratio of pressure and thermal relaxation time scales, whereas Appendix H highlights the influence of the interfacial area.

2. Governing equations of the two-phase flow model and main properties

We first introduce the set of governing equations of the two-phase flow models examined in the sequel. These include the mass balance equations, the momentum and energy balance equations, together with the evolution
of the statistical fractions. We also refer the reader to some companion references [3, 13, 26, 27, 29, 30, 32, 34, 37, 38, 48, 55, 60] that may help and provide additional details.

Both gas–liquid flows (without any mass transfer), and liquid–vapour flows, which involve a unique component (basically water in our framework), will be examined in the sequel. Thus, we introduce rather logical notations as follows.

The statistical fractions of the immiscible liquid phase and the gas/vapour phase are noted \( \alpha_l(x, t) \) and \( \alpha_{g,v}(x, t) \) (for gas and vapour respectively). They are such that:

\[
\alpha_l(x, t) + \alpha_{g,v}(x, t) = 1. \tag{1}
\]

In order to ease notations, we will favour the liquid phase (indexed by \( l \)) in both cases. All variables in the gas (respectively the vapour) phase will be indexed by \( g \) (respectively by \( v \)).

Within the \( k \)-phase, and for \( k \in \{l, g\} \) or \( k \in \{l, v\} \), \( U_k, P_k, \rho_k, m_k = \alpha_k \rho_k \) and \( E_k \) will respectively denote the phasic mean velocity, mean pressure, mean density, mass fraction and mean total energy, setting:

\[
E_k = \rho_k (\epsilon_k(\rho_k, P_k) + U_k^2/2) \tag{2}
\]

where \( \epsilon_k(\rho_k, P_k) \) denotes the internal energy within phase \( k \). The gas–liquid state variable \( W^{lg} \) will be noted:

\[
W^{lg} = (\alpha_l, m_l, m_g, m_l U_l, m_g U_g, \alpha_l E_l, \alpha_g E_g) \tag{3}
\]

while the liquid–vapour state variable will correspond to:

\[
W^{lv} = (\alpha_l, m_l, m_v, m_l U_l, m_v U_v, \alpha_l E_l, \alpha_v E_v). \tag{4}
\]

In the sequel, in order to ease notations, the state variable is called \( W \); \( W \) can refer to \( W^{lg} \) or \( W^{lv} \), depending on the current treated case. If no precision is given, then the results stand true for both cases.

### 2.1. Open set of equations

We may now write the governing set of PDE, which correspond to balance equations for mass, momentum and energy, within phase \( k \), and for the statistical fraction \( \alpha_l \). These are:

\[
\begin{cases}
\hat{\alpha}_l(\alpha_l) + \nabla (W) \nabla \alpha_l = \phi_l(W); \\
\hat{\alpha}_l(m_k) + \nabla \cdot (m_k U_k) = \Gamma_k(W); \\
\hat{\alpha}_l(m_k U_k) + \nabla \cdot (m_k U_k \otimes U_k + \alpha_k P_k \mathcal{I}) - \Pi_l(W) \nabla \alpha_k = S_{Q_k}(W); \\
\hat{\alpha}_l(\alpha_k E_k) + \nabla \cdot (\alpha_k U_k (E_k + P_k)) + \Pi_l(W) \hat{\alpha}_l(\alpha_k) = S_{E_k}(W)
\end{cases} \tag{5}
\]

for \( k \in \{l, g\} \), or \( k \in \{l, v\} \), and noting \( \mathcal{I} \) the identity matrix.

When focusing on gas–liquid flows, we obviously have:

\[
\Gamma_l(W) = \Gamma_g(W) = 0, \tag{6}
\]

whereas for liquid–vapour flows, the following constraint holds:

\[
\Gamma_l(W) + \Gamma_v(W) = 0. \tag{7}
\]

For \( k \in \{l, g\} \), or \( k \in \{l, v\} \), interfacial transfer terms arising in momentum and energy balance equations, comply with:

\[
\sum_k S_{E_k}(W) = 0 \tag{8}
\]

together with:

\[
\sum_k S_{Q_k}(W) = 0. \tag{9}
\]
2.2. Entropy-consistent closure laws

We assume that the interfacial velocity \( \mathcal{V}_I(W) \) takes the form:

\[
\mathcal{V}_I(W) = \beta(W)U_l + (1 - \beta(W))U_{v,g}
\]

with \( \beta(W) \in [0,1] \). Hence, it satisfies Galilean invariance. We will specify later on some scalar functions \( \beta(W) \) that will guarantee unique field by field jump conditions (see also the reference paper \[13\]). The next definitions require introducing phasic entropies \( S_k(\rho_k, P_k) \) and temperatures \( T_k(\rho_k, P_k) \), which are such that:

\[
c_k^2 \hat{\rho}_k(S_k(\rho_k, P_k)) + \hat{\rho}_k(S_k(\rho_k, P_k)) = 0,
\]

where:

\[
\rho_k c_k^2 = \left( \frac{P_k}{\rho_k} - \rho_k \hat{\rho}_k(\epsilon_k(\rho_k, P_k)) / (\hat{\rho}_k(\epsilon_k(\rho_k, P_k))) \right)
\]

and:

\[
\frac{1}{T_k} = \frac{\hat{\rho}_k(S_k(\rho_k, P_k))}{\hat{\rho}_k(\epsilon_k(\rho_k, P_k))}.
\]

Using the latter definitions, we get the admissible interfacial pressure \( \Pi_I(W) \) as:

\[
\Pi_I(W) = \chi(W)P_l + (1 - \chi(W))P_{v,g}
\]

where the function \( \chi(W) \) is obtained straightforwardly:

\[
\chi(W) = \frac{(1 - \beta(W))T_{v,g}}{(1 - \beta(W))T_{v,g} + \beta(W)T_l}.
\]

We emphasize that this enables to recover the standard Baer–Nunziato closure \( \Pi_I(W) = P_l, \mathcal{V}_I(W) = U_{g,v} \).

It also guarantees the Realisable Interfacial Pressure condition (see Appendix F and \[43\]). We recall now some classical results.

**Property 1** (Structure of the one-dimensional convective subset). We restrict to the one-dimensional framework. We have the following results:

- The homogeneous convective part (left-hand side) of system (5) is hyperbolic. The seven real eigenvalues read:

\[
\begin{align*}
\lambda_0(W) &= \mathcal{V}_I(W); \\
\lambda_1(W) &= U_l - c_l; \\
\lambda_2(W) &= U_l; \\
\lambda_3(W) &= U_l + c_l; \\
\lambda_4(W) &= U_{v,g} - c_{v,g}; \\
\lambda_5(W) &= U_{v,g}; \\
\lambda_6(W) &= U_{v,g} + c_{v,g}.
\end{align*}
\]

Right eigenvectors span the whole space away from the resonance state:

\[
|U_k - \mathcal{V}_I(W)| = c_k.
\]

- For \( k \in (l, v) \) or \( k \in (l, g) \), waves associated with eigenvalues \( U_k \pm c_k \) are Genuinely Non-Linear, and waves associated with eigenvalues \( U_k \) are Linearly Degenerate.

- The coupling wave associated with \( \lambda_0(W) \) is Linearly Degenerate if:

\[
\beta(W)(1 - \beta(W)) = 0
\]

or if:

\[
\beta(W) = \frac{m_l}{m_l + m_{v,g}}.
\]

- System (5) can be symmetrized away from resonant states (17).
The proof of the first three points can be found in [13], while the fourth one is available in [15]. Moreover, details pertaining to Riemann invariants within fields associated with eigenvalues \( \lambda_{1-6} \) can also be found in the latter references. Even more, explicit analytic forms of Riemann invariants in the coupling wave can be found in the particular case \( \beta(W) = 0 \) in [13, 20]. Owing to the LD structure of the coupling wave, when \( \beta(W) \) is chosen in a suitable way, unique jump conditions may be defined in GNL fields for system (5). This was pointed out in [13], and a direct consequence is that the computation of shocks is meaningful in that case, since non-conservative products are well-defined in shock waves (in the non-resonant case): convergent approximations of shocks are not scheme dependent (see [35]).

Now, coming back to the three-dimensional setting, we introduce the entropy – entropy flux pair \( (\eta, F_\eta) \):

\[
\eta = \sum_k m_k S_k(\rho_k, P_k), \quad \mathcal{F}_\eta = \sum_k m_k S_k(\rho_k, P_k) U_k.
\]

Considering smooth solutions, we can examine the time evolution of \( \eta \) in system (5). Straightforward calculations enable to get:

\[
\partial_t(\eta) + \nabla \cdot (\mathcal{F}_\eta) = \text{RHS}_\eta(W)
\]

with an explicit form of the right-hand side \( \text{RHS}_\eta(W) \) depending on the closure laws for \( \phi_l(W), \Gamma_l(W), S_{Q_k}(W) \) and \( S_{E_k}(W) \).

In order to ease the presentation and calculations, we rewrite source terms in a slightly different form and define translated unknowns \( D_k(W) \) and \( \psi_k(W) \) such that:

\[
\begin{align*}
D_k(W) &= S_{Q_k}(W) - \frac{U_l + U_{v,g}}{2} \Gamma_k(W); \\
\psi_k(W) &= S_{E_k}(W) - V_I^E(W) D_k(W) - \frac{U_l U_{v,g}}{2} T_k(W).
\end{align*}
\]

Taking interfacial constraints on \( S_{Q_k}(W) \) and \( S_{E_k}(W) \) into account, we must fulfil:

\[
D_l(W) + D_{v,g}(W) = 0,
\]

and also:

\[
\psi_l(W) + \psi_{v,g}(W) = 0.
\]

We consider a consistent and Galilean invariant formulation for \( V_I^E(W) \), hence:

\[
V_I^E(W) = \beta^E(W) U_l + (1 - \beta^E(W)) U_{v,g}
\]

where \( \beta^E(W) \) must lie in \([0, 1]\). We classically note in the sequel:

\[
\mu_k = h_k - T_k S_k
\]

where the free enthalpy \( h_k \) writes:

\[
h_k = c_k(\rho_k, P_k) + \frac{P_k}{\rho_k}.
\]

Eventually, considering the notations:

\[
\begin{align*}
\Delta P &= P_l - P_{v,g}, \\
\Delta U &= U_l - U_{v,g}, \\
\Delta T &= T_l - T_{v,g}, \\
\Delta \mu &= \frac{\mu_l}{T_l} - \frac{\mu_{v,g}}{T_{v,g}}.
\end{align*}
\]

we obtain the following classical result ([3, 18, 25, 38, 49, 55]).
**Property 2** (Entropy consistent source terms for a class of two-phase flow models). We consider the following source terms:

\[
\begin{align*}
\phi_l(W) &= K(W)\Delta P, \\
D_l(W) &= -d(W)\Delta U, \\
\psi_l(W) &= -q(W)\Delta T, \\
\Gamma_l(W) &= -\Lambda(W)\Delta \mu.
\end{align*}
\] (29)

Then smooth solutions of system (5) agree with:

\[
\partial_t \eta + \nabla \cdot (\mathcal{F}_\eta) = \text{RHS}_\eta(W) \geq 0
\] (30)

providing positive functions \(K(W), d(W), q(W), \Lambda(W)\).

**Proof.** The proof is simple. The right-hand side term \(\text{RHS}_\eta\) is simply:

\[
\text{RHS}_\eta = \frac{1}{T_l T_{v,g}} \psi_l(W)(T_{v,g} - T_l) + \left(\frac{1 - \beta^E(W)}{T_l} + \frac{\beta^E(W)}{T_{v,g}}\right) D_l(W)(U_{v,g} - U_l)
\]

\[
+ \left(\frac{1 - \chi(W)}{T_l} + \frac{\chi(W)}{T_{v,g}}\right) \phi_l(W)(P_l - P_{v,g}) + \left(\frac{\mu_{v,g}}{T_{v,g}} - \frac{\mu_l}{T_l}\right) \Gamma_l(W)
\] (31)

and thus positive, owing to (29).

Note that the second, third and fourth closure laws arising in (29) are also entropy-consistent when focusing on single-pressure two-fluid six-equation models [46]. Closure laws for heat transfer and drag coefficients arising in \(q(W)\) and \(d(W)\) can be taken from the standard literature (see [46] among others). Besides, references [7,8,28,44] provide closure laws for the pressure relaxation time scales \(\tau_P(W)\) involved in \(K(W)\).

### 2.3. Relaxation process in a class of two-phase flow models

When focusing on gas–liquid flows, where no mass transfer occurs, a straightforward question arises, which concerns the (physically expected) decay of velocity, pressure and temperature gaps. Note that this problem has been investigated recently in [43], while focusing on the sole pressure gaps, though examining several two-phase or multiphase flow models. While restricting to the present class of gas–liquid two-phase flow models, the problem at stake here is whether the whole relaxation process is active for the three quantities \(\Delta P\), \(\Delta U\) and \(\Delta T\). For that purpose, we consider some homogeneous situation with no gradient of mean variables, thus considering an initial condition for system (5), such that:

\[
\nabla \psi(x, t = 0) = 0
\] (33)

whatever \(\psi\) stands for. Hence, system (5) reduces to:

\[
\begin{align*}
\partial_t (\alpha_l) &= \phi_l(W); \\
\partial_t (m_k) &= 0; \\
\partial_t (m_k U_k) &= S_{Q_k}(W); \\
\partial_t (\alpha_k E_k) + \Pi_l(W) \partial_t (\alpha_k) &= S_{E_k}(W),
\end{align*}
\] (34)

\[\text{Consider the vector } \Delta \text{ defined at each point } (x, t), \text{ the components of which are quantity discrepancies between phases, corresponding to states that make the source terms vanish. If the solution of the governing equations, without any convective term, complies with:}
\]

\[
\partial_t (\|\Delta\|_{L^2}) \leq 0
\] (32)

then the relaxation process is said to be effective.
for \( k \in \{l, g\} \). This system may be rewritten in a slightly different form:
\[
\begin{align*}
\dot{c}_i(\alpha_l) &= \phi_l(W); \\
\dot{c}_i(\alpha_lE_l) + \Pi_l(W)\dot{c}_i(\alpha_l) &= S_{E_l}(W); \\
\dot{c}_i(m_lU_l) &= S_{Q_l}(W); \\
\dot{c}_i(m_l) &= \dot{c}_i(m_g) = 0; \\
\dot{c}_i(m_lU_l + m_gU_g) &= 0; \\
\dot{c}_i(\alpha_lE_l + \alpha_gE_g) &= 0.
\end{align*}
\]

Equipped with this system (34), we may write the governing equations for the three quantities \( \Delta P, \Delta U \) and \( \Delta T \).

If we note:
\[
\Delta^g = (\Delta U, \Delta T, \Delta P)^T
\]

simple calculations enable to get:
\[
\dot{c}_i(\Delta^g) = -\mathcal{R}^g(W)\Delta^g
\]

where the matrix \( \mathcal{R}^g(W) \in \mathcal{M}_3(\mathbb{R}) \) is given by:
\[
\mathcal{R}^g(W) = \begin{pmatrix}
d^g_{UU}(W) & 0 & 0 \\
d^g_{UT}(W) & d^g_{TT}(W) & d^g_{TP}(W) \\
d^g_{PU}(W) & d^g_{PT}(W) & d^g_{PP}(W)
\end{pmatrix}
\]

Coefficients in matrix \( \mathcal{R}^g(W) \) read:
\[
d^g_{UU}(W) = d(W)\left(\frac{1}{m_l} + \frac{1}{m_g}\right),
\]

together with\(^1\):
\[
\begin{align*}
d^g_{UT}(W) &= d(W)\Delta U\left(\frac{\beta^e(W) - 1}{m_e(R_l(T_l))_\rho_l} + \frac{\beta^e(W)}{m_g(R_g(T_g))_\rho_g}\right), \\
d^g_{TT}(W) &= q(W)\left(\frac{1}{m_e(R_l(T_l))_\rho_l} + \frac{1}{m_g(R_g(T_g))_\rho_g}\right), \\
d^g_{TP}(W) &= K(W)\left(\frac{1}{m_e(R_l(T_l))_\rho_l} + \frac{1}{m_g(R_g(T_g))_\rho_g}\right),
\end{align*}
\]

and:
\[
\begin{align*}
d^g_{PU}(W) &= d(W)\Delta U\left(\frac{\beta^e(W) - 1}{m_e(R_l(T_l))_\rho_l} + \frac{\beta^e(W)}{m_g(R_g(T_g))_\rho_g}\right), \\
q^g_{PT}(W) &= q(W)\left(\frac{1}{m_e(R_l(T_l))_\rho_l} + \frac{1}{m_g(R_g(T_g))_\rho_g}\right), \\
d^g_{PP}(W) &= K(W)\left(A_l + A_g + \left(\frac{\chi(W) - 1}{m_e(R_l(T_l))_\rho_l} + \frac{\chi(W)}{m_g(R_g(T_g))_\rho_g}\right)\Delta P\right).
\end{align*}
\]

We have used the following notation here for \( k = l, g \):
\[
A_k = \frac{\rho_k c_k^2}{\alpha_k}.
\]

Thus, we get:
\(\text{\textsuperscript{1}}\)Considering the internal energies \( \epsilon_k \), with some abuse of notation, we will note in the sequel every change of variable of the functions \( \epsilon_k(P_k, T_k) = \epsilon_k(\rho_k, S_k) = \epsilon_k(\rho_k, L_k) = \epsilon_k(P_k, S_k) = \epsilon_k(\rho_k, T_k) \) as \( \epsilon_k(P_k, T_k) = \epsilon_k(\rho_k, S_k) = \epsilon_k(\rho_k, P_k) = \epsilon_k(P_k, S_k) = \epsilon_k(\rho_k, T_k) \).

\(\text{\textsuperscript{2}}\)The symbol \( \dot{c}_i(\alpha_l) \) should be replaced by: \( \dot{c}_i(\alpha_l) = \mu_l(W)\dot{c}_i(\alpha_l) \).
Property 3 (Relaxation effects in a class of gas–liquid flow models). We assume that equations of state within each phase are such that, for \( k = l, g \):

\[
0 \leq \hat{c}_{T_k}(\epsilon_k)|_{\rho_k}.
\]

(43)

Considering positive functions \( K(W), q(W), d(W) \), the relaxation process is guaranteed for solutions of (34), if eigenvalues of matrix \( \mathcal{R}_l^g(W) \) are real and positive, or if they are complex with a positive real part. This is guaranteed if the pressure gap \( \Delta P \) is sufficiently small in the following sense:

\[
(P_g - P_l) \left( \frac{\chi(W) - 1}{\rho_l \hat{c}_l(\epsilon_l)|_{\rho_l}} \right) \leq \frac{\chi(W)\alpha_l}{\rho_g \hat{c}_g(\epsilon_g)|_{\rho_g}} \leq \alpha_g \rho_l c_l^2 + \alpha_l \rho_g c_g^2,
\]

(44)

and if the following condition holds:

\[
\frac{a_{TT}^g(W)a_{PP}^g(W) - a_{TP}^g(W)q(W)K(W)}{q(W)K(W)} > 0.
\]

(45)

**Proof.** The proof is simple and can be found in [42]. We briefly recall it below.

- First, note that \( \lambda = a_{UU}^l(W) \) is an obvious real eigenvalue of matrix \( \mathcal{R}_l^g(W) \), and is positive.
- The remaining two eigenvalues of \( \mathcal{R}_l^g(W) \) are the two solutions \( \lambda_\pm \) of the second-order polynomial:

\[
p(\lambda) = \lambda^2 - \left( a_{TT}^g(W) + a_{PP}^g(W) \right)\lambda + a_{TT}^g(W)a_{PP}^g(W) - a_{TP}^g(W)q(W).
\]

(46)

Owing to conditions (43) and (44), the sum \( a_{TT}^g(W) + a_{PP}^g(W) \) is positive, thus:

- In case of complex eigenvalues, these are complex conjugate, and their real part \( a \) is equal to \( (a_{TT}^g(W) + a_{PP}^g(W))/2 \), thus positive;
- If the two eigenvalues \( \lambda_\pm \) are real, we have: \( \lambda_+ + \lambda_- = a_{TT}^g(W) + a_{PP}^g(W) \), thus the sum is positive. Moreover, the product \( \lambda_+ \lambda_- \) is equal to:

\[
a_{TT}^g(W)a_{PP}^g(W) - a_{TP}^g(W)q(W)
\]

(47)

and we can conclude that both \( \lambda_+ \) and \( \lambda_- \) are positive, owing to (45).

\[\square\]

For sake of clarity, conditions (43)–(45) are specified and discussed below for various EOS. To do so, we consider the specific case used in the sequel which is: \( \chi(W) = 0 \) and thus \( \Pi_l = P_g \).

- First, we note that condition (43) stands true in most EOS as it corresponds to a specific capacity at constant volume, which is expected to be positive.
- For a mixture of perfect gases:

\[
P_k = \rho_k(\gamma_k - 1)\epsilon_k.
\]

(48)

Conditions (44) and (45) always hold true, whatever the state variable \( W \) is.

- For a mixture of Stiffened-Gases we have:

\[
\begin{aligned}
P_k + \gamma_k \Pi_k &= \rho_k(\gamma_k - 1)(\epsilon_k - \epsilon_{k_0}) \\
C_{\text{ex}} T_k &= \epsilon_k - \epsilon_{k_0} - \frac{\Pi_k}{\rho_k}
\end{aligned}
\]

(49)

where \( \gamma_k > 1, \Pi_k > 0 \) and \( \epsilon_{k_0} \) are constants. Admissible states are such that: \( P_k + \Pi_k > 0 \) and \( \epsilon_k - \epsilon_{k_0} > 0 \). Close to thermodynamic equilibrium, equation (44) is obviously satisfied. Condition (44) may be rewritten as:

\[
\alpha_g \left( P_l + \Pi_l \right) + (\alpha_l \gamma_g + \alpha_g(\gamma_l - 1)) \left( P_g + \Pi_g \right) + \alpha_g(\gamma_l - 1) \left( \Pi_l - \Pi_g \right) > 0.
\]

(50)
Equation (50) shows that, if $\tilde{\Pi}_l > \tilde{\Pi}_g$, condition (44) holds true, even far from thermodynamic equilibrium, in the admissible range: $P_k + \tilde{\Pi}_k > 0$, $k \in \{l, g\}$.

Condition (45) is equivalent to:

$$
(m_l C_{v_l} + m_g C_{v_g}) \left[ \frac{p_l c_l^2}{\alpha_l \gamma_l} + \frac{p_g c_g^2}{\alpha_g \gamma_g} \right] \geq \left( \tilde{\Pi}_l - \tilde{\Pi}_g \right) \left[ \frac{\tilde{\Pi}_g - \tilde{\Pi}_l}{T_g} + \frac{P_g - P_l}{T_l} + \frac{\tilde{\Pi}_l (T_l - T_g)}{T_l T_g} \right].
$$

(51)

It must be emphasized that, close to the thermodynamic equilibrium, the right-hand side of (51) behaves as $-(\tilde{\Pi}_l - \tilde{\Pi}_g)^2/T_g$, and thus condition (45) is satisfied. This is an expected property as the entropy may be understood as a Lyapunov function of our system, owing to the closure of source terms (see Property 2). Condition (51) – and thus (45) –, no longer holds, for any admissible state $W$, far from equilibrium.

- For a mixture of Noble-Abel Stiffened-Gases [50] we have:

$$
\begin{align*}
P_k + \gamma_k \tilde{\Pi}_k &= \frac{\rho_k (\gamma_k - 1)}{1 - \rho_k b_k} (\epsilon_k - \bar{\epsilon}_{k_0}) \\
C_{v_k} T_k &= \epsilon_k - \bar{\epsilon}_{k_0} - \frac{(1 - \rho_k b_k) \tilde{\Pi}_k}{\rho_k}
\end{align*}
$$

(52)

where $\gamma_k > 1$, $\tilde{\Pi}_k > 0$, $b_k > 0$ and $\bar{\epsilon}_{k_0}$ are constants. Admissible states are such that: $P_k + \tilde{\Pi}_k > 0$, $(1 - \rho_k b_k) > 0$ and $\epsilon_k - \bar{\epsilon}_{k_0} > 0$.

Condition (44) writes as:

$$
(\gamma_l - 1) (P_l - P_g) < (1 - \rho_l b_l) \left( \rho_l c_l^2 + \frac{\alpha_l}{\alpha_g} \rho_g c_g^2 \right).
$$

(53)

Condition (45) is identical to the one exhibited for a mixture of Stiffened Gases (51).

In practice, for complex EOS, conditions (44) and (45) have to be checked in computer codes, in particular far from the thermodynamic equilibrium.

**Remark 1.** – We may also note that the threshold effect on $\Delta P$ arising in condition (44) has already been pointed out in [6]. It arises when taking energy balance into account, and it does not exist when restricting to the barotropic case (see [41]). Its counterpart in the framework of immiscible three-phase flows and miscible two-phase flows is discussed in [43]. Straightforward numerical applications show that it can be hardly violated in practice. Thus, the latter constraint is indeed very weak. Actually, we may note that a simpler sufficient condition guarantees that it holds, whatever the values of statistical fractions are, which is:

$$
|\Delta P| \left| \frac{1}{\rho_l c_l^2 P_l (\epsilon_l)} \right| + \left| \frac{1}{\rho_g c_g^2 P_g (\epsilon_g)} \right| \leq \min(\rho_l c_l^2, \rho_g c_g^2).
$$

(54)

- Moreover, a glance at the precise form of condition (45) shows that the relative amplitudes of time scales $\tau_P(W)$ and $\tau_T(W)$ respectively involved in closure laws of $K(W)$ and $q(W)$ have no impact on the latter condition.
- When accounting for mass transfer terms arising in liquid–vapour flow models, some additional constraints may arise, as emphasized in [42].

### 2.4. Relaxation time scales: $\tau_P$, $\tau_T$, $\tau_m$ and $\tau_U$

In order to close system (5), the functions $q(W)$, $K(W)$, $\Lambda(W)$ and $d(W)$ are to be given and thus, four positive relaxation time scales $\tau_P$, $\tau_T$, $\tau_m$ and $\tau_U$ must be introduced.

- Pressure relaxation coefficient:

$$
K(W) = \frac{\alpha_l \alpha_g v}{\tau_P \mathcal{P}_0}
$$

(55)

with $\mathcal{P}_0$ a positive reference pressure.
– Heat transfer relaxation coefficient:

\[ q(W) = \frac{m_l C_{vl} m_g C_{v_g, v}}{\tau_T (m_l C_{vl} + m_g C_{v_g, v})} \]  

(56)

– Mass transfer relaxation coefficient:

\[ \Lambda(W) = \frac{m_l m_v}{\tau_m (m_l + m_g) \Gamma_0} \]  

(57)

with \( \Gamma_0 \) a positive reference fraction of \( \mu_T \).

– Drag relaxation coefficient:

\[ d(W) = \frac{m_l m_{g,v}}{\tau_U (m_l + m_{g,v})} \]  

(58)

Different forms of \( \tau_P, \tau_T, \tau_m \) and \( \tau_U \) arise from the literature \([4, 7, 8, 19, 28, 46, 54]\). Some of them will be detailed in the following sections.

3. Finite volume techniques to compute system (5)

We restrict herein to the computation of unsteady two-phase flows, while applying the two-fluid approach, and considering (5). Before going further on, we rewrite in a quite formal way system (5) as follows:

\[ \partial_t(W) + \nabla \cdot (F(W)) + C(W) \nabla \alpha_l = S(W) \]  

(59)

where \( W \) denotes the so-called conservative variable introduced in (3) or (4). Thus, \( F(W) \) denotes the conservative flux accounting for convective effects, while \( C(W) \) collects non-conservative contributions arising from the left-hand side of (5). Eventually, \( S(W) \) accounts for the right-hand side source terms in (5).

We emphasize that, in the sequel, we assume that shock relations are uniquely defined in model (5), and thus we will restrict for our applications to closure laws for the interfacial velocity \( \mathcal{V}_I \) detailed in Property 1, or other suitable laws that comply with the LD structure of the coupling wave \( \lambda_0(W) = \mathcal{V}_I(W) \). Of course, this provides a suitable framework in order to verify algorithms (while computing the error), when shocks occur in the flow.

Due to specific applications including water-hammer, loss of coolant accidents, steam explosion and other extreme situations including shock structures and high energy transfers between fluids or phases, robust algorithms are required, and for that purpose, focus is usually given first on low-order time-space Finite Volume schemes (see \([21, 33]\)).

In this framework, a simple way to compute approximate solutions of system (5) consists in using the following hybrid implicit/explicit time scheme:

\[ \text{vol}(\Omega_i)\left(W_i^{n+1} - W_i^n - \Delta t^n (S(W))^{n+1}_i\right) = -\int_{\Omega_i} \int_{t^n}^{t^{n+1}} \left(\nabla \cdot (F(W)) + C(W) \nabla \alpha_l\right)^n \, dx \, dt \]  

(60)

setting: \( \Delta t^n = t^{n+1} - t^n \), noting \( \text{vol}(\Omega_i) \) the volume of cell \( \Omega_i \), and using an explicit approximate Riemann solver associated with the hyperbolic system (evolution step):

\[ \partial_t(W) + \nabla \cdot (F(W)) + C(W) \nabla \alpha_l = 0 \]  

(61)

in order to get \( W_i^{n+1} \) solution of:

\[ \text{vol}(\Omega_i)\left(W_i^{n+1} - W_i^n\right) + \Delta t^n \int_{\Omega_i} \left(\nabla \cdot (F(W)) + C(W) \nabla \alpha_l\right)^n \, dx = 0 \]  

(62)

in such a way that the entropy inequality holds true. Afterwards, the solution \( W_i^{n+1} \) of the relaxation step:

\[ \text{vol}(\Omega_i)\left(W_i^{n+1} - W_i^{n+1} - \Delta t^n (S(W))_i^{n+1}\right) = 0 \]  

(63)
must be found within each cell.

This strategy has been used by many authors, in order to compute two-phase or multiphase flows (see among others [6, 18, 25, 55]). Actually, it is rather well-suited for transient flows including shock waves, owing to the fact that:

- the implicit relaxation step enables to get rid of too heavy constraints linked with upper bounds on the time step;
- the explicit scheme involved in the evolution step is in some sense optimal in terms of accuracy, when focusing on fast pressure waves impinging solid structures, and meanwhile it automatically provides the dynamical time stepping.

Obviously, as it occurs in the single phase framework for weakly compressible flows, other numerical strategies should be preferred when aiming at computing low velocity flows, as proposed for instance quite recently in [56].

Before going further on, we would like to recall some suitable algorithms that provide meaningful approximations in the evolution step (61). Among others, note first that the simple Rusanov solver [57] may be applied for that purpose. Moreover, four distinct schemes providing accurate approximations of the homogeneous part of the Baer–Nunziato model are:

- an approximate Godunov scheme, which has first been proposed in [61];
- a relaxation scheme that was then introduced in [14, 58] and extended in [59] for three-phase flow;
- an HLLC approximate Riemann solver, which was proposed in [64];
- another relaxation scheme that was described in [2].

The reader is referred to the paper [16] which provides a detailed comparison of $L^1$ norm of errors for the latter schemes, while focusing on test cases involving difficult Riemann problems. It also seems worth mentioning the recent Discontinuous Galerkin scheme described in [17]. Eventually, we point out the recent work [62] dedicated to the analysis of the Riemann problem associated with the Baer–Nunziato model.

For all the simulations run in this paper, a robust Rusanov scheme [57] adapted for the handling of non-conservative products is used.

We will now focus on two different strategies in order to get approximations of the set of coupled ODE:

$$
\dot{W}_t(W) = S(W). \tag{64}
$$

In the sequel, we will consider:

$$
\begin{align*}
\forall_{t}(W) &= U_t \\
\Pi_{t}(W) &= P_{g,v}.
\end{align*} \tag{65}
$$

3.1. Discrete source terms for gas–liquid flow models

The strategy consists in simulating the drag effects and thermodynamic effects separately. This approach can be justified by the block triangular structure of matrix $\mathbb{R}^{lg}$, see (38). Hence, the simulation of the source terms contains two steps:

$$
\begin{array}{c}
\text{I : } W^n \xrightarrow{\text{Velocity relaxation}} W^{n+1} \\
\text{II : } W^{n+1} \xrightarrow{\text{Thermodynamic relaxation process}} W^{n+1}.
\end{array}
$$

The same time step $\Delta t^n$ is used within each step. The velocity relaxation process is taken from [25] and recalled in Appendix B.

*For sake of readability, in Sections 3.1 and 3.2, the state $W^{n+1}$ will be referred as $W^n$ and $\Delta t^n$ will be mentioned as $\Delta t$. }
### 3.1.1. Two approaches for the computation of the thermodynamic source terms

First, we recall that for a quantity \( \Psi \), \( \Delta \Psi \) is set as:

\[
\Delta \Psi \quad \Psi_l \quad \Psi_g.
\]

(66)

Two algorithms are detailed in order to simulate the thermodynamic part of the model (5) in the case of a mix of liquid and gas (i.e. without mass transfer).

**A – Fractional step algorithm**

A first possible approach in order to account for source terms (34) is to use a fractional step scheme, which decouple (35). System (35), without the velocity relaxation (\( d(W) = 0 \)), is simulated in two implicit steps:

\[
\begin{align*}
\text{I : } & W^* & \xrightarrow{\text{Pressure relaxation}} & W^{n+1} \\
\text{II : } & W^n & \xrightarrow{\text{Heat transfer}} & W^* \\
\end{align*}
\]

The time step \( \Delta t \), given by the evolution step, is used for computing step I and step II. This idea of decoupling system (34) is quite standard and is already used in the literature (see [26, 56] for example).

**I – The pressure relaxation algorithm**

This step is similar but different to the one used in [26]. It simulates the solution of the following system:

\[
\begin{align*}
\hat{c}_l(\alpha_l) &= K(W)\Delta P; \\
\hat{c}_l(m_k) &= 0; \quad (k \in \{l, g\}) \\
\hat{c}_l(m_k U_k) &= 0; \quad (k \in \{l, g\}) \\
\hat{c}_l(m_l\epsilon_l + m_g\epsilon_g) &= 0 \\
\hat{c}_l(\tilde{\rho}) + P\hat{c}_l(\alpha_l) &= 0.
\end{align*}
\]

(67)

The equation (67.4) allows writing:

\[
\xi_n = m_l^n \epsilon_l^n + m_g^n \epsilon_g^n = m_l^n \epsilon_l^n + m_g^n \epsilon_g^n > 0.
\]

(68)

Solution of (67) also complies with:

\[
\hat{c}_l(S_g) = 0.
\]

(69)

Thus:

\[
S_g^n = S_g^n.
\]

(70)

Using the definition of the sound speed, one can derive from (67):

\[
\hat{c}_l(\Delta P) = -a_{PP}\Delta P
\]

(71)

setting:

\[
a_{PP} = K(W)\left(\frac{\rho_l c_l^2}{\alpha_l} + \frac{\rho_g c_g^2}{\alpha_g} - \frac{1}{m_l \epsilon_{P_l}(\epsilon_l)_\rho l}\Delta P\right).
\]

(72)

It can be noted that the coefficient \( a_{PP} \) is the one arising in \( A_{lg} \), see (38).

The pressure relaxation algorithm consists in three steps\(^2\).

\(^2\)Given a thermodynamic function \( \Psi \), with some abuse of notation, we still note in the sequel every change of variable of the function \( \Psi(P, T) = \Psi(\rho, S) = \Psi(P, \rho) = \Psi(P, S) = \Psi(\rho, T) \) as \( \Psi(P, T) = \Psi(\rho, S) = \Psi(P, \rho) = \Psi(P, S) = \Psi(\rho, T) \).
Pressure relaxation algorithm

**Step 1.** Compute an approximate solution of (71) with an implicit Euler time discretization by considering the frozen coefficient $a_{P_P}$ at time $t^n$:

$$\Delta P^n* = \frac{1}{1 + a_{P_P} \Delta t} \Delta P^n.$$  \(73\)

**Step 2.** Using the constraint (70) on the entropy $S^n* = S^n_g$ and the conservation law of the sum of the internal energies (67.4), define:

$$\begin{align*}
P^n* &:= P^n* - \Delta P^n* \\
\rho^n* &:= \rho_{g}\left(P^n*, S^n*\right) \\
\epsilon^n* &:= \frac{\xi - m^n* \varsigma_{g}(P^n*, S^n*)}{m^n*}.
\end{align*}$$  \(74\)

Then compute $P^n_l*$ by inverting the immiscible constraint:

$$\frac{m^n_l}{\rho_l(P^n_l*, \epsilon^n*)} + \frac{m^n_g}{\rho^n*} - 1 = 0 \Leftrightarrow G(P^n_l*) = 0.$$  \(75\)

**Step 3.** Update the statistical fractions $\alpha^n_l*$ and $\alpha^n_g*$:

$$\begin{align*}
\alpha^n_l* &= \frac{m^n_l}{\rho_l(P^n_l*, \epsilon^n*)} \\
\alpha^n_g* &= 1 - \alpha^n_l*.
\end{align*}$$  \(76\)

and the total energies:

$$\begin{align*}
\alpha^n_l* E^n_l* &= m^n_l \epsilon^n* + \frac{1}{2} m^n_l (U^n_l)^2 \\
\alpha^n_g* E^n_g* &= \alpha^n_l* E^n_l + \alpha^n_g* E^n_g - \alpha^n_l* E^n_l*.
\end{align*}$$  \(77\)

Thus, we have:

**Property 4** (Pressure relaxation algorithm).

- The pressure relaxation process is effective during step 1 if the pressure gap satisfies condition (44).
- For any mixture of two generalized stiffened gas EOS, the solution $P^n_l*$ of step 2, in the admissible range, exists and is unique. Moreover, $\alpha^n_l* \in [0, 1]$.

**Proof.** - If the pressure gap satisfies (44), then the coefficient $a_{P_P}$ is positive and the discrete equation (73) is a contraction whatever the time step is.
- Let us consider a mixture of two generalized stiffened gases:

$$\begin{align*}
\left(\gamma_k - 1\right) \rho_k (\epsilon_k - \epsilon_{k_0}) &= P_k + \gamma_k \bar{\Pi}_k \\
S_k - s_{k_0} &= C_{v_k} \log \left(\epsilon_k - \epsilon_{k_0} - \frac{\bar{\Pi}_k}{\rho_k} \rho_k^{1-\gamma_k}\right)
\end{align*}$$  \(78\)

with $\bar{\Pi}_k$ a positive constant and $\epsilon_{k_0}$ and $s_{k_0}$ constants.

Let us recall the constraint for the pressure in the case of a generalized stiffened gas:

$$P_k + \bar{\Pi}_k > 0.$$  \(79\)
Thanks to (70), one can obtain:

$$\alpha_{\eta}^* = m_{\eta}^n (\gamma_k - 1) \frac{1}{\gamma_k} \exp\left(\frac{S_{\eta}^n - s_{80}}{\gamma_k E_{\eta}}\right) \left(P_l^n - \Delta P_l^* + \hat{\Pi}_{\eta}\right) \gamma_k^{-1}.$$

(80)

By enforcing (67.4) one can deduce:

$$\epsilon_l^* = \frac{1}{m_l^n} \left(\xi_l - \alpha_{\eta}^* \frac{P_l^n - \Delta P_l^* + \gamma_g \hat{\Pi}_g}{\gamma_g - 1} - m_g^n \epsilon_{g0}\right).$$

(81)

The immiscible constraint (1) can then be rewritten as follows:

$$\frac{(\gamma_l - 1) \left( (m_l \epsilon_l)_{\eta}^* - m_l^n \epsilon_{l0} \right)}{P_l^n + \gamma_l \Pi_l} + m_g^n (\gamma_g - 1)^{1/\gamma_g} \exp\left(\frac{S_{g}^n - s_{80}}{\gamma_g E_{g}}\right) \left(P_g^n - \Delta P_g^* + \hat{\Pi}_g\right) \gamma_g^{-1} - 1 = 0.$$

(82)

Which can be seen as:

$$H(P_l) = 0.$$  

(83)

Standard calculations show that the function $H$ is decreasing and, using (79), that the bounds are:

$$\begin{cases}
\lim_{P_l \to -\infty} H(P_l) = -1 \\
\lim_{P_l \to \max(-\Pi_l, \Delta P_l - \Pi_g)} H(P_l) = +\infty
\end{cases}$$

(84)

which enables to conclude for $P_l^n$, such that $P_l^n + \Pi_l > 0$ and $P_g^n + \Pi_g > 0$.

Thus, $\alpha_l^* \in [0, 1]$, owing to (80) and (82).

II – The temperature relaxation algorithm

It simulates the solutions of the following system:

$$\begin{cases}
\hat{\partial}_l(\alpha_l) = 0 \\
\hat{\partial}_l(m_k) = 0 \quad (k \in \{l, g\}) \\
\hat{\partial}_l(m_k U_k) = 0 \quad (k \in \{l, g\}) \\
\hat{\partial}_l(m_l \epsilon_l + m_g \epsilon_g) = 0 \\
m_l \hat{\partial}_l(\epsilon_l) + m_g \hat{\partial}_g(\epsilon_g) = -q(W) \Delta T.
\end{cases}$$

(85)

The evolution of the temperature gap $\Delta T$ can be deduced from (85), it reads:

$$\hat{\partial}_l(\Delta T) = -\alpha_{TT} \Delta T$$

(86)

setting:

$$\alpha_{TT} = q(W) \left(\frac{1}{m_l \hat{\partial}_l(\epsilon_l)_{\rho_l}} + \frac{1}{m_g \hat{\partial}_g(\epsilon_g)_{\rho_g}}\right).$$

(87)

With $\alpha_{TT}$ arising in the matrix $\mathcal{R}^{lg}$, see (38).

The temperature relaxation algorithm consists in three steps.
Temperature relaxation algorithm

Step 1. Compute an approximate solution of the equation (86) with an implicit Euler time discretization by considering the coefficient $a_{TT}$ frozen at the time $t^n$:

$$\Delta T^{n+1} = \frac{1}{1 + a_{TT}^* \Delta t} \Delta T^n.$$  \hspace{1cm} (88)

Step 2. Since $\alpha_l$ is constant throughout this step, and considering the conservation law of the sum of the internal energies (85.4), $T_l^{n+1}$ is solution of:

$$m_l^n \epsilon_l \left( \rho_l^n, T_l^{n+1} \right) + m_g^n \epsilon_g \left( \rho_g^n, T_l^{n+1} - \Delta T^{n+1} \right) = \xi_n.$$  \hspace{1cm} (89)

Step 3. Update the thermodynamic quantities $T_l^{n+1} = T_l^{n+1} - \Delta T^{n+1}$, and the total energies:

$$\begin{cases}
(\alpha_l E_l)^{n+1} = m_l^n \epsilon_l \left( \rho_l^{n*}, T_l^{n+1} \right) + \frac{1}{2} m_l^n (U_l^n)^2 \\
(\alpha_g E_g)^{n+1} = \alpha_l^{n*} E_l^{n*} + \alpha_g^{n*} E_g^{n*} - \alpha_l^{n+1} E_l^{n+1}.
\end{cases}$$  \hspace{1cm} (90)

We get:

Property 5 (Temperature relaxation algorithm).

- Step 1 guarantees the relaxation process for the temperature throughout this algorithm, whatever the time step is.
- Considering a mixture of two generalized stiffened gas EOS, the solution $T_l^{n+1}$ of step 2 in the admissible range exists and is unique.

Proof. As the coefficient $a_{TT}$ is positive, the discretized equation of evolution of $\Delta T$ (88) is a contraction.

- For a mixture of two generalized stiffened gases, the temperature at time $t^{n+1}$ is:

$$T_l^{n+1} = \frac{1}{m_l^n C_{v_l} + m_g^n C_{v_g}} \left( \xi_n + m_g^n C_{v_g} \Delta T^{n+1} - \left( m_l^n \epsilon_{l_0} + m_g^n \epsilon_{g_0} + \dot{\Pi}_l \alpha_l^{n*} + \dot{\Pi}_g \left( 1 - \alpha_g^{n*} \right) \right) \right).$$  \hspace{1cm} (91)

□

B – Coupled algorithm

The basic idea of this new algorithm consists in simulating the thermodynamic relaxation effects in one step. The governing set of equations is as follows:

$$\begin{align*}
\partial_t (m_k) &= 0 \quad (k \in \{l, g\}) \\
\partial_t (m_k U_k) &= 0 \quad (k \in \{l, g\}) \\
\partial_t (m_l \epsilon_l + m_g \epsilon_g) &= 0 \\
\partial_t (\alpha_l) &= K(W) \Delta P \\
\partial_l (\alpha_l) &= -q(W) \Delta T.
\end{align*}$$  \hspace{1cm} (92)

Using (92) one can obtain:

$$\partial_l \left( \frac{\Delta P}{\Delta T} \right) = -\mathcal{R}_{PT} \left( \frac{\Delta P}{\Delta T} \right)$$  \hspace{1cm} (93)

with:

$$\mathcal{R}_{PT} = \begin{pmatrix} a_{PP} & a_{PT} \\ a_{TP} & a_{TT} \end{pmatrix}.$$  \hspace{1cm} (94)
Matrix $\mathcal{R}_{PT}$ is a sub-matrix of matrix $\mathcal{R}^g$ (38):

$$
\begin{align}
\alpha_{PT} &= K(W) \left( A_t + A_g - \frac{1}{m_i e_{\gamma_i}(\epsilon_i)} \Delta P \right) \\
\alpha_{PT} &= q(W) \left( \frac{1}{m_i e_{\gamma_i}(\epsilon_i)} \right) \\
\alpha_{PT} &= K(W) \left( \frac{1}{m_i e_{\gamma_i}(\epsilon_i)} \right) \\
\alpha_{PT} &= q(W) \left( \frac{1}{m_i e_{\gamma_i}(\epsilon_i)} \right)
\end{align}
$$

The coupled algorithm reads as follows.

**Coupled (P-T) relaxation algorithm**

**Step 1.** Compute an approximate solution of system (93), with the evolution matrix $\mathcal{R}_{PT}$ frozen at time $t^n$, using an implicit Euler scheme:

$$
\left( \frac{\Delta P}{\Delta T} \right)^{n+1} = (\mathcal{I}_2 + \Delta t \mathcal{R}_{PT})^{-1} \left( \frac{\Delta P}{\Delta T} \right)^n
$$

where $\mathcal{I}_2$ is the identity matrix in $\mathcal{M}_2(\mathbb{R})$.

**Step 2.** Set:

$$
\begin{align}
\xi_n &= m_i \xi_i(P_t^n, T_t^n) + m_g \xi_g(P_g^n, T_g^n) \\
T_{g}^{n+1} &= T_{g}^{n+1} - \Delta T_{g}^{n+1} \\
P_{g}^{n+1} &= P_{g}^{n+1} - \Delta P_{g}^{n+1}.
\end{align}
$$

Compute $P_{l}^{n+1}$ and $T_{l}^{n+1}$, solutions of the following system:

$$
\begin{align}
\frac{m_i^n \xi_i(P_{l}^{n+1}, T_{l}^{n+1}) + m_g^n \xi_g(P_{g}^{n+1}, T_{g}^{n+1})}{n(P_{l}^{n+1}, T_{l}^{n+1}) + \rho_g(P_{g}^{n+1}, T_{g}^{n+1})} &= \xi_n \\
\end{align}
$$

**Step 3.** Update $\alpha_{l}^{n+1}$:

$$
\alpha_{l}^{n+1} = \frac{m_i^n}{\rho_l(P_{l}^{n+1}, T_{l}^{n+1})}
$$

and the total energies:

$$
\begin{align}
(\alpha_l E_l)^{n+1} &= m_i^n \xi_i(P_{l}^{n+1}, T_{l}^{n+1}) + \frac{1}{2} m_i^n (U_{l}^{n+1})^2 \\
(\alpha_g E_g)^{n+1} &= \alpha_l^n E_l^n + \alpha_g^n E_g^n - (\alpha_l E_l)^{n+1}.
\end{align}
$$

Before going further on, we introduce the following lemma:

**Lemma 1.** For a system of the form:

$$
\xi Y(W) = -A(W)Y(W)
$$

with $Y \in \mathbb{R}^j$ and $A \in \mathcal{M}_j(\mathbb{R})$, $j \in \mathbb{N}$, discretized by using an implicit Euler scheme as:

$$
(\mathcal{I}_j + \Delta t A^n)Y^{n+1} = Y^n
$$

with $\mathcal{I}_j$ the identity of $\mathcal{M}_j(\mathbb{R})$. If the real part of every eigenvalue of $A^n$ is positive, then system (102) ensures that:

$$
\| Y^{n+1} \|_2 \leq \| Y^n \|_2
$$

and that system (102) is invertible, whatever the time step is.
Proof. As $A^n \in \mathcal{M}_j(\mathbb{R})$, its eigenvalues $\lambda_1, \ldots, \lambda_j$ are in $\mathbb{C}$:

$$\forall k \in [1, j], \quad \lambda_k = a_k + ib_k.$$  

(104)

Then, the eigenvalues $\lambda_1^r, \ldots, \lambda_j^r$ of the matrix $(I_j + \Delta t A^n)^{-1}$ are:

$$\forall k \in [1, j], \quad \lambda_k^r = \frac{1}{1 + a_k \Delta t + ib_k \Delta t}.$$  

(105)

Assuming that the real parts of the eigenvalues of $A^n$ are positive:

$$\forall k \in [1, j], \quad a_k > 0$$  

(106)

then,

$$\forall \Delta t > 0, \forall k \in [1, j], \quad \|1 + a_k \Delta t + ib_k \Delta t\| > 1.$$  

(107)

Whatever the time step is, this ensures that system (102) is invertible and that:

$$\|Y_n+1\|_2 \leq \|Y_n\|_2.$$  

(108)

\[\square\]

Then, one can obtain:

**Property 6** (Coupled P-T relaxation algorithm).

- If the pressure gap satisfies condition (44), then equation (96) ensures the relaxation process of the pressure and the temperature over time whatever the time step is, if (45) holds.
- Given a mixture of two perfect gas EOS, the solution of (98) in the admissible range, exists and is unique. Moreover, the discrete statistical fraction $\alpha_{l+1}$ belongs to $[0, 1]$.

**Proof.** – If conditions (44) and (45) are verified, then the real parts of the eigenvalues of $\mathcal{R}_{PT}$ are positive. Thus, Lemma 1 applies and equation (96) ensures the relaxation process over time, whatever the time step is.

- Let us consider a mixture of two perfect gases:

\[
\begin{cases}
(\gamma_k - 1) \rho_k \epsilon_k = P_k \\
\epsilon_k = C_v T_k.
\end{cases}
\]  

(109)

Then it can be deduced from the conservation law of the sum of the internal energies (92.3) that:

$$T_{l+1} = \frac{\xi_l + m^g_2 C_v \Delta T_{l+1}}{m^l n^l C_v + m^g_2 C_v}.$$  

(110)

Inserting (109) and (110) in (98.2), one can obtain:

$$\Theta(P_{l+1}^n) = \frac{m^l n^l (\gamma_l - 1) C_v T_{l+1}^n}{P_{l+1}^n} + \frac{m^g_2 (\gamma_g - 1) C_v (T_{l+1}^n - \Delta T_{l+1})}{P_{l+1}^n - \Delta P_{l+1}} - 1 = 0.$$  

(111)

Standard calculations show that the function $\Theta(P_l)$ is decreasing and that its bounds are:

$$\begin{cases}
\lim_{P_l \to +\infty} \Theta(P_l) = -1 \\
\lim_{P_l \to \max(0, \Delta P)} \Theta(P_l) = +\infty
\end{cases}$$  

(112)

which enables to conclude for $P_{l+1}^n$, such that $P_{l+1}^n + \Pi_l > 0$ and $P_{l+1}^n + \Pi_g > 0$. Moreover, as $k \in \{l, g\}$, $T_k = \frac{P_k + \Pi_k}{\rho_k C_v k (\gamma_k - 1)}$, temperatures $T_l$ and $T_g$ are in the admissible range.

Thus, $\alpha_{l+1}^n \in [0, 1]$, owing to (111).

\[\square\]
Remark 2. For a mixture of Stiffened Gas EOS, system (98) is fully coupled. Equation (98.1) writes:

$$\begin{align*}
T_l^{n+1} &\left(\frac{\gamma_l - 1}{P_l^{n+1} + \Pi_l} C_{v_l} + \frac{\gamma_g - 1}{P_g^{n+1} + \Pi_g} C_{v_g}\right) + m^g C_{v_g} \left(1 + \frac{(\gamma_g - 1)\Pi_g}{P_g^{n+1} - \Delta P^{n+1} + \Pi_g}\right) = \xi_n + \hat{E}_{n+1}, \\
\hat{E}_{n+1} &= -m^g \epsilon_{g,n} - m^g \epsilon_{g,0} + m^g C_{v_g} \Delta T^{n+1} \left[1 + \frac{(\gamma_g - 1)\Pi_g}{P_g^{n+1} - \Delta P^{n+1} + \Pi_g}\right].
\end{align*}$$

Moreover, equation (98.2) reads:

$$m_i^n \frac{(\gamma_l - 1)C_{v_l} T_l^{n+1}}{P_l^{n+1} + \Pi_l} + m_g^n \frac{(\gamma_g - 1)C_{v_g} (T_l^{n+1} - \Delta T^{n+1})}{P_g^{n+1} - \Delta P^{n+1} + \Pi_g} = 1. \tag{114}$$

3.1.2. Verification and comparison between the two approaches in a homogeneous case

The basic idea for the two approaches detailed before is to deduce from system (34) an equation of evolution of the gap of the thermodynamics quantities. The main advantage of this idea is that it can ensure the relaxation process between the phases over time, giving conditions that can be easily verified inside a code. The main difference is whether system (34) is simulated in one step or “decoupled”. In this section, the two approaches are numerically compared. To do so, the flow is supposed to be homogeneous:

$$\forall \Psi(W), \ \partial_x \Psi(W) = 0 \tag{115}$$

and velocities within each phase are assumed to be null. This simulation can be viewed as the return to thermodynamics equilibrium of a two-phase flow inside a box. The different simulations are performed with time steps ranging between $10^{-10}$ s and $10^{-2}$ s. All relaxation time scales are supposed to be constant. Their values, the initial conditions and the coefficients of the EOS for the different cases are given in Appendix A. Moreover, in order to ensure an effective relaxation time of each separated effect close to the relaxation time scale given by the user, the value of $\mathcal{R}_0$ has to be set at $t = 0$ to:

$$\mathcal{R}_0 = \left| \alpha^0_c \rho^0_i (c^0_i)^2 + \alpha^0_t \rho^0_v (c^0_v)^2 - \alpha^0_\gamma \frac{\Delta \rho^0}{\rho^0_i \partial_\rho (\partial_\rho_i) | \rho^0_1 \right| \right|. \tag{116}$$

The fractional step algorithm obviously does not capture the correct behaviour of the pressure $P_l$ at the origin for coarse time steps in some cases (see Fig. 1). Actually, it can lead to a huge overestimation of the pressure, whereas the coupled algorithm better follows the monotony of the exact solution (see Fig. 2). For example, in Figure 1, the pressure $P_l$ for large time steps can be ten times bigger than the one obtained with the coupled approach. The relaxation process overtime is effective in case 1 as it can be seen in Figures 3 and 4. Here, owing to (50), and since $\Pi_l > \Pi_g$, condition (44) is automatically satisfied. Nonetheless, condition (45) must be checked inside the code – see Section 2.3–. Figures 5 and 6 show that the two numerical methods give similar results on the temperature profiles in this case. The main difference between the two numerical approaches here lays in the liquid pressure profiles.

In order to evaluate the performance of these two numerical schemes, a convergence study has been conducted. Let us introduce the error $E_\Psi(t, \Delta t)$ of a thermodynamic quantity $\Psi$ for a time step $\Delta t$ at time $t$. Given the numerical approximate solution $\Psi_{ap}$ of $\Psi_{ex}$, the error $E_\Psi(t, \Delta t)$ is calculated as follows:

$$E_\Psi(t, \Delta t) = \frac{|\Psi_{ex}(t) - \Psi_{ap}(N\Delta t)|}{|\Psi_{ex}(t = 0)|} \tag{117}$$

with:

$$t_l = N\Delta t. \tag{118}$$

In our cases we set $t_l = 2.0 \times 10^{-3}$ s.
TWO APPROACHES TO COMPUTE UNSTEADY COMPRESSIBLE TWO-PHASE FLOW MODELS

Figure 1. Homogeneous case: evolution of the pressure $P_l$ in case 1 ($\tau_p = 10^{-5}$ s and $\tau_T = 10^{-3}$ s), computed with the fractional step algorithm. The initial conditions are given in Appendix A.

Figure 2. Homogeneous case: evolution of the pressure $P_l$ in case 1 ($\tau_p = 10^{-5}$ s and $\tau_T = 10^{-3}$ s), computed with the coupled algorithm. The initial conditions are given in Appendix A.

The convergence curves (see Figs. 7 and 8) show a speed of convergence close to 1 for the two approaches, as expected theoretically. It is worth noting that the value of the error can be quite large for the fractional step algorithm, as it can be two hundred times bigger than the error of the coupled algorithm for the pressure $P_l$, see Figure 8. The plateau of convergence for large time steps corresponds to simulations where $\Delta t > t_t$.

Moreover, for a given value of $\Delta t$, the ratio of computational costs is between 2 and 8 in favour of the coupled algorithm, depending on the mesh size, see Table 1.
Figure 3. Homogeneous case: evolution of $\Delta P = P_l - P_g$ in case 1 ($\tau_P = 10^{-5} s$ and $\tau_T = 10^{-3} s$), computed with the fractional step algorithm. The initial conditions are given in Appendix A.

Figure 4. Homogeneous case: evolution of $\Delta P = P_l - P_g$ in case 1 ($\tau_P = 10^{-5} s$ and $\tau_T = 10^{-3} s$), computed with the coupled algorithm. The initial conditions are given in Appendix A.
Figure 5. Homogeneous case: evolution of $T_l$ and $T_g$ in case 1 ($\tau_P = 10^{-5}$ s and $\tau_T = 10^{-3}$ s), computed with the fractional step algorithm. The initial conditions are given in Appendix A.

Figure 6. Homogeneous case: evolution of $T_l$ and $T_g$ in case 1 ($\tau_P = 10^{-5}$ s and $\tau_T = 10^{-3}$ s), computed with the coupled algorithm. The initial conditions are given in Appendix A.

Remark 3. It is also worth noting that the accuracy of the fractional step algorithm decreases when the ratio $\tau_P/\tau_T$ tends to zero (see Appendix G).
Figure 7. Homogeneous case: convergence curve for case 1. The initial conditions are given in Appendix A.

Figure 8. Homogeneous case: convergence curve for case 5. The initial conditions are given in Appendix A.

**Figure 9.** Sketch of the data settings in meters.

**A – Experimental set up and numerical settings**

This part aims at validating the coupled scheme by comparing its results with the experiment [11] (see [10] for further details). The experimental set-up is made up of a one-dimensional shock tube composed of air and a layer of liquid droplets. It contains, at $t = 0$ (see Fig. 9 for a sketch of this set up), a high pressure chamber (HP), followed by a zone at atmospheric pressure. Inside the low pressure chamber, a cloud of droplets (CD) with a unique diameter ($D_d = 500 \mu m$) lies between $x = 3.0$ m and $x = 3.40$ m.

The initial conditions are set as follows [11]:

<table>

</table>

In the experimental set-up, several pressure probes are set throughout the tube [11]. They give the value of the total pressure. The total pressure $P_{\text{mix}}$ is defined as:

$$P_{\text{mix}} = \sum_k \alpha_k P_k.$$  \hspace{1cm} (119)

Indeed, setting:

$$Q = \sum_k m_k U_k$$  \hspace{1cm} (120)

and using (5), we have:

$$\partial_t(Q) + \nabla \cdot \left( \sum_k m_k U_k \otimes U_k \right) + \nabla P_{\text{mix}} = 0.$$  \hspace{1cm} (121)
Integrating (121) over a closed domain shows that the pressure applied on the walls is precisely $P_{\text{mix}}$, i.e. the total pressure measured experimentally.

The value of $P_{\text{mix}}$ is compared with the experimental data on three probes:

- $S_1$ located at $x = 1.77$ m. This station is located inside the initial gaseous area.
- $S_2$ located at $x = 3.08$ m. This station is located at the beginning of the initial layer of droplets.
- $S_3$ located at $x = 3.19$ m. This station is located in the middle of the initial cloud of droplets.

In this configuration, the fragmentation of the water droplets plays a substantial role in the dynamic, according to [31]. That is why an interfacial area $\mathcal{A}$ is introduced for the liquid phase:

$$\mathcal{A} = \frac{6\alpha_l}{D_d}$$  \hspace{1cm} (122)

The equation of evolution of the interfacial area (see Appendix C) and its numerical treatment are taken from [5]. The velocity relaxation process has to be computed too. To do so, the algorithm detailed in [25] has been used and is recalled in Appendix B. In order to simulate this shock tube, stiffened gas EOS (see (78)) are used in each phase. The values of the thermodynamic coefficients are given in Appendix A.

Moreover, the relaxation time scales $\tau_U$, $\tau_P$ and $\tau_T$ are chosen as follows.

Velocity relaxation time scale:

$$\frac{1}{\tau_U} = \frac{0.125(m_l + m_g)\|U_l - U_g\|}{\rho_l D_d}.$$  \hspace{1cm} (123)

This expression of $\tau_U$ is derived from the Stokes formula [46].

Pressure relaxation time scale:

$$\tau_P \mathcal{P}_0 = \frac{4\pi}{3}\mu_g = \frac{1}{\tau_P} = \frac{3\mathcal{P}_0}{4\pi\mu_g},$$  \hspace{1cm} (124)

where $\mu_g = 1.8 \times 10^{-5}$ kg m$^{-1}$ s$^{-1}$ is the dynamic viscosity of the air at 1 bar and 293 K. It is the limit of the closure law proposed in [28] for small diameter droplets.

Temperature relaxation time scale:

$$\frac{1}{\tau_T} = \frac{6\alpha_l Nu \lambda_g (m_l C_{v_l} + m_g C_{v_g})}{m_l C_{v_l} m_g C_{v_g} D_d^2},$$  \hspace{1cm} (125)

where $Nu = 10$ is the Nusselt number and $\lambda_g = 0.6$ (W m$^{-1}$ K$^{-1}$) is the thermal conductivity of the gas phase. This form is taken from [54].

The simulations have been performed using one-dimensional meshes including 1000, 10 000 and 20 000 cells. The CFL number is set to 0.45 and provides the time stepping.

**B – Numerical results and comparison with experimental data**

We recall that the Weber number, $We$, is a dimensionless number that quantifies the atomization of the droplets. Introducing $\sigma_d$, a positive reference surface tension, $We$ is defined as:

$$We = \frac{\rho_l \|U_l - U_g\|^2 D_d}{\sigma_d}.$$  \hspace{1cm} (126)

More precisely, if the Weber number is smaller than a certain threshold called the critical Weber number $We_c$, then the atomization does not occur (see Appendix C). Two critical Weber numbers will be tested in the simulations: $We_c = 3$ and $We_c = 12$. These values, respectively suggested for liquid water and liquid aluminium droplets, are taken from [54]. The total pressure $P_{\text{mix}}$ obtained through numerical simulations is compared with the experimental data.

First, let us note that on Figures 10–12, the experimental data have been translated of a fixed value $t_{\text{translate}} = 0.0019$ s, so that the experimental and simulated incident shock waves are synchronized on station 3. As the
Figure 10. Chauvin experiment: evolution of the pressure \( P_{\text{mix}} \) (Pa) at station 3, using two different critical Weber numbers: \( We_c = 3 \) or 12. Meshes contain: 1000 cells, 10 000 cells or 20 000 cells. CFL = 0.45.

Figure 11. Chauvin experiment: evolution of the pressure \( P_{\text{mix}} \) (Pa) at station 2 for various meshes and \( We_c \).
Figure 12. Chauvin experiment: evolution of the pressure $P_{\text{mix}}$ (Pa) at station 1 for various meshes.

Experimental and numerical shock waves arrive almost at the same time at the station 1 and 2, it can be concluded that the simulation captures well the celerity of the shock wave. On fine meshes, Figures 10 and 11 show a pressure drop right after the incident shock wave of 2.4 bar. The amplitude of the incident shock wave is overestimated by the simulation by 10\% at station 3 (Fig. 10), whereas there is almost no discrepancy between the simulation and the experimental data at stations 1 and 2. The pressure loss right after the shock wave is expected as it accounts for the atomization of the water droplets, see [31]. A coarse mesh with 1000 cells is not sufficient to properly capture this phenomenon. In Figure 10, after the pressure loss, the total pressure increases and then plateaus around 3.5 bar, considering $We_c = 3$ and a 20000 cells mesh. Focusing on this mesh, the numerical results overestimate the experimental data on $P_{\text{mix}}$ by about 7\% on station 3, 10\% on station 2 and 2\% on station 1. Eventually, the total pressure decreases due to the arrival of the reflected rarefaction wave coming from the left wall boundary. It is also worth noting that $\Delta P$ remains lower than $2 \times 10^{-3}$\% of the initial phasic pressure throughout the simulation. On the other hand, $\Delta T$ remains lower than 2\% of the initial phasic temperature gap.

The numerical simulation of Chauvin experiment [11] using the fractional step approach can be found in Section 4.3 of [6]. On a fine mesh, discrepancies between the two approaches on the total pressure profile are less than 1\% on the incident shock wave amplitude, and about 5\% on the pressure plateau.

In addition, these numerical simulations also show the influence of the critical Weber number – i.e. how the interfacial area is taken into account – on the overall behaviour of the solution after the shock wave, inside the cloud of collapsible droplets. Indeed, as shown in [12], an accurate modelling of the inter-facial area evolution is a key ingredient in order to capture the correct behaviour of the pressure profile after the shock. Herein, computational results are closer to the experimental data when using $We_c = 3$ on a refined mesh, as anticipated.

According to Figure 13, the velocity of the liquid phase (labelled one) and the gas phase (labelled two) are completely distinct, with a maximum gap of more than 200 m s$^{-1}$, right after the incident shock wave. The structural hypothesis of velocity disequilibrium between phases is thus retrieved in the numerical results. Figure 14 shows the impact of the value of the critical Weber number on the atomization process. Indeed, a
Figure 13. Chauvin experiment: evolution of the velocities at station 3 for a mesh of 20,000 cells. Index number 1 corresponds to the liquid phase and index number 2 corresponds to the gaseous phase.

Figure 14. Chauvin experiment: evolution of the diameter $D_d$ at station 3 for a mesh of 20,000 cells.
four times bigger critical Weber number results here in a twice larger droplet’s diameter on the first plateau after the shock.

In Appendix H, the Chauvin experiment [11] is also computed, assuming rigid particles, as conducted by authors in [12]. In that case, as the diameter of the droplets is constant, no pressure drop arises right after the incident shock wave, as expected (see Fig. 3 of [12], and also [6]), even for a refined mesh.

3.2. Discrete source terms for a mixture of liquid water and vapour

As in the liquid–gas section, the velocity relaxation is taken into account before the thermodynamic part of the source terms.

3.2.1. Two algorithms for the simulation of the thermodynamic source terms

We recall that for \( \Psi \in \{ P, T, U \} \), \( \Delta \Psi \) is set as:

\[
\Delta \Psi = \Psi_l - \Psi_v.
\]  
(127)

And for clarity, we note:

\[
\Delta \mu = \frac{\mu_l}{T_l} - \frac{\mu_v}{T_v}.
\]  
(128)

A – Fractional step approach

For a mixture of water and vapour, the relaxation effects, which are presented for a mixture of liquid and gas, must be complemented with the mass transfer terms. This fractional step scheme is thus composed of three steps, one for each thermodynamic effect. The sequence is as follows, still using the same time step \( \Delta t \) within each step:

\[
\begin{align*}
& \text{I : } W^n \xrightarrow{\text{Pressure relaxation}} W^n^* \\
& \text{II : } W^n^* \xrightarrow{\text{Heat transfer}} W^n^*^+ \\
& \text{III : } W^n^*^+ \xrightarrow{\text{Mass transfer}} W^{n+1}.
\end{align*}
\]

The first two steps are identical to the ones presented for a mixture of liquid and gas in Section 3.1.1.A. Besides, step III is taken from [18] and recalled in Appendix D.

B – Coupled approach

Once more, the basic idea of this approach is to account for all the thermodynamic effects in one step. First, the global system of source terms is recalled:

\[
\begin{align*}
& \partial_t(\alpha_l) = K(W) \Delta P \\
& \partial_t(m_l) = \Gamma_l(W) \\
& \partial_t\left(m_l U_l\right) = \frac{U_l + U_v}{2} \Gamma_l(W) \\
& \partial_t(\alpha_l E_l) + P_e \partial_t(\alpha_l) = \frac{U_l U_v}{2} \Gamma_l(W) - q(W) \Delta T \\
& \partial_t(m_l + m_v) = 0 \\
& \partial_t(m_l U_l + m_v U_v) = 0 \\
& \partial_t(\alpha_l E_l + \alpha_v E_v) = 0.
\end{align*}
\]  
(129)
From system (129), it can be obtained:

\[
\begin{aligned}
\dot{\epsilon}_t(\alpha_l) &= K(W)\Delta P \\
\dot{\epsilon}_t(m_i) &= \Gamma_t(W) \\
\dot{\epsilon}_t(m_i\epsilon_i) &= \frac{U_i + U_v}{2} \Gamma_t(W) \\
\dot{\epsilon}_t(m_i\epsilon_i) + P_v\dot{\epsilon}_t(\alpha_l) &= -q(W)\Delta T \\
\dot{\epsilon}_t(m_i + m_v) &= 0 \\
\dot{\epsilon}_t(m_i U_l + m_v U_v) &= 0 \\
\dot{\epsilon}_t(\alpha_l E_l + \alpha_v E_v) &= 0.
\end{aligned}
\]

(130)

It can also be deduced from system (130) that:

\[
\dot{\epsilon}_t(m_i\epsilon_i + m_v\epsilon_v) = 0
\]

(131)

since:

\[
\dot{\epsilon}_t(m_i U_l^2) = \frac{U_i U_v}{2} \Gamma_t = -\dot{\epsilon}_t(m_v U_v^2).
\]

(132)

System (130) can be recast in two subsystems, which are:

\[
\begin{aligned}
\dot{\epsilon}_t(\alpha_l) &= K(W)\Delta P \\
\dot{\epsilon}_t(m_i) &= \Gamma_t \\
\dot{\epsilon}_t(m_i\epsilon_i) &= -P_v K(W)\Delta P - q(W)\Delta T \\
\dot{\epsilon}_t(m_i + m_v) &= 0 \\
\dot{\epsilon}_t(m_i\epsilon_i + m_v\epsilon_v) &= 0
\end{aligned}
\]

and:

\[
\begin{aligned}
\dot{\epsilon}_t(m_i U_l) &= \frac{U_i + U_v}{2} \Gamma_t \\
\dot{\epsilon}_t(m_i U_l + m_v U_v) &= 0.
\end{aligned}
\]

(133)

System (133) can be solved first, independently of system (134).

From system (133), an equation of evolution for the thermodynamic quantity gaps can be derived, see [42]:

\[
\dot{\epsilon}_t \begin{pmatrix}\Delta P \\ \Delta T \\ \Delta \mu \end{pmatrix} = -\mathcal{R}_{PT}\begin{pmatrix} \Delta P \\ \Delta T \\ \Delta \mu \end{pmatrix}.
\]

(135)

The coefficients of \(\mathcal{R}_{PT}\in\mathcal{M}_3(\mathbb{R})\) are detailed in [42] and recalled in Appendix E.

Using an implicit Euler method, system (135) is discretized as follows:

\[
\begin{pmatrix} \Delta P \\ \Delta T \\ \Delta \mu \end{pmatrix}^{n+1} = \left(1 + \Delta t\mathcal{R}_{PT}\right)^{-1} \begin{pmatrix} \Delta P \\ \Delta T \\ \Delta \mu \end{pmatrix}^n.
\]

(136)

The conservation laws included in (133) imply:

\[
\begin{aligned}
M_n &= m_i^n + m_v^n = m_i^{n+1} + m_v^{n+1} \\
\xi_n &= (m_i\epsilon_i)^n + (m_v\epsilon_v)^n = (m_i\epsilon_i)^{n+1} + (m_v\epsilon_v)^{n+1}
\end{aligned}
\]

(137)

and the one included in (134) gives:

\[
Q_n = (m_i U_l)^n + (m_v U_v)^n = (m_i U_l)^{n+1} + (m_v U_v)^{n+1}.
\]

(138)
**Coupled (P-T, $\mu$) relaxation algorithm**

**Step 1.** Compute $\Delta P^{n+1}$, $\Delta T^{n+1}$ and $\Delta \mu^{n+1}$, solution of system (136). The matrix $\mathcal{A}_{PT\mu}$ is considered frozen at time $t^n$.

**Step 2.** Compute $m_l^{n+1}$ as:

$$m_l^{n+1} = \frac{M_n}{1 + \left(\frac{M_n - m_l^n}{m_l^n}\right) \exp\left(\frac{\Delta \mu^{n+1}}{m_l^n} \Delta t\right)} > 0.$$  \hspace{1cm} (139)

Deduce $m_v^{n+1} = M_n - m_l^{n+1} > 0$ and set $\Gamma_l^{n+1} = \frac{m_v^{n+1} - m_v^n}{\Delta t}$.

**Step 3.** Compute $P_l^{n+1}$ and $T_l^{n+1}$, solutions of the following system:

$$\begin{cases} m_l^{n+1} \epsilon_l(P_l^{n+1}, T_l^{n+1}) + (M_n - m_l^{n+1}) \epsilon_v(P_l^{n+1} - \Delta P^{n+1}, T_l^{n+1} - \Delta T^{n+1}) = \xi_n \\ \rho(P_l^{n+1}, T_l^{n+1}) + \rho_v(P_l^{n+1}-\Delta P^{n+1}, T_l^{n+1}-\Delta T^{n+1}) = 1. \end{cases}$$ \hspace{1cm} (140)

**Step 4.** Update $P_v^{n+1}$, $T_v^{n+1}$, $\alpha_l^{n+1}$ and $\alpha_v^{n+1}$ as:

$$\begin{cases} P_v^{n+1} = P_v^{n+1} - \Delta P^{n+1} \\ T_v^{n+1} = T_v^{n+1} - \Delta T^{n+1} \\ \alpha_l^{n+1} = \frac{m_l^{n+1}}{\rho(P_l^{n+1}, T_l^{n+1})} \\ \alpha_v^{n+1} = 1 - \alpha_l^{n+1}. \end{cases}$$ \hspace{1cm} (141)

Update $\epsilon_l^{n+1}$ and $\epsilon_v^{n+1}$ in agreement with (140).

**Step 5.** Then compute $U_l^{n+1}$ and $U_v^{n+1}$ solutions of:

$$\begin{cases} (m_l U_l)^{n+1} - (m_l U_l)^n = \Delta t \frac{m_l^{n+1}}{2} (U_l^{n+1} + U_v^{n+1}) \\ (m_v U_v)^{n+1} - (m_v U_v)^n = -\Delta t \frac{m_v^{n+1}}{2} (U_l^{n+1} + U_v^{n+1}). \end{cases}$$ \hspace{1cm} (142)

**Step 6.** Update the total energies as:

$$\begin{cases} (\alpha_l E_l)^{n+1} = m_l^{n+1} \epsilon_l(P_l^{n+1}, T_l^{n+1}) + \frac{1}{2} m_l^{n+1} (U_l^{n+1})^2 \\ (\alpha_v E_v)^{n+1} = \alpha_v E_v^n + (\alpha_l E_l)^n - (\alpha_l E_l)^{n+1}. \end{cases}$$ \hspace{1cm} (143)

**Remark 4.** – Equation (139) is deduced from the mass conservation (133.2), with $\Delta \mu$ frozen at time $t^{n+1}$.
– System (140) is derived from the conservation law of the sum of the internal energies (131) and the immiscible constraint (1).
– System (142) is derived from system (134) by using an implicit Euler scheme.

Thus, we have:

**Property 7** (Coupled P-T-$\mu$ algorithm).

– System (142) is invertible whatever the time step is.
– If the three fundamentals minors of matrix $\mathcal{A}_{PT\mu}$ (135) are positive, then step 1 ensures the thermodynamic relaxation process over time, whatever the time step is.
– For a given couple of perfect gas EOS, solutions $P_l^{n+1}$ and $T_l^{n+1}$ of (140) in the admissible range, exist and are unique. Moreover, $\alpha_l^{n+1}$ belongs to $[0,1]$ and the partial masses $m_l^{n+1}$ and $m_v^{n+1}$ remain positive.

**Proof.** – Standard calculations give the determinant $\delta$ of system (142):

$$\delta = \frac{1}{2} \left( m_l^{n+1} m_v^n + m_v^n m_l^{n+1} \right).$$ \hspace{1cm} (144)

As $\delta$ is strictly positive whatever the time step is, system (142) is always invertible.

- System (140) is identical to (98), thus it benefits from the same properties.
- If the three fundamentals minors of $\mathcal{R}_{PT\mu}$ (135) are positive, then according to [42], Lemma 1 applies and ensures the relaxation process over time, whatever the time step is.

\[ \Box \]

3.2.2. Verification and comparison between the two approaches in a homogeneous case

In this section, the two schemes presented in the previous part are compared on different test cases. To do so, the flow is supposed to be homogeneous:

\[ \forall \Psi(W), \partial_t \Psi(W) = 0 \]  

(145)

and the velocities within each phase are assumed to be null. The different simulations are performed with time steps ranging between $10^{-10}$ s and $10^{-1}$ s. All the relaxation time scales are supposed to be constant. Their values, the initial conditions and the coefficients of the EOS for the different cases are given in Appendix A.

Moreover, in order to ensure an effective relaxation time of each separated effect close to the relaxation time scale given by the user, the value of $\mathcal{P}_0$ and $\Gamma_0$ have to be set at $t = 0$ to:

\[
\begin{align*}
\mathcal{P}_0 &= \left\| \frac{\alpha_0 \rho_0^0 \left( e_0^0 \right)^2 + \alpha_0 \rho_0 \left( e_0 \right)^2 - \alpha_w \frac{\Delta \rho}{\rho_0^0 (\epsilon_0 (\epsilon_0)) \epsilon_0}} \right\|, \\
\Gamma_0 &= \frac{m_v^0 \left( \gamma_0 C_v t + \frac{e_0}{T_0} \left( 2 + \frac{\gamma_0}{\gamma_v} \left( 2 + \frac{e_0}{C_v T_0} \right) \right) \right) + m_v^0 \left( \gamma_v C_v t \right)}{\left( 2 + \frac{e_0}{C_v T_0} \right)}. 
\end{align*}
\]

(146)

As it occurs in the liquid–gas framework, the fractional step algorithm can in some cases overestimate the pressure of the liquid phase for coarse time steps. For example, in case 3, (see Fig. 15), using a time step of $10^{-3}$ s, the latter method leads to pressure values almost one hundred times bigger than the converged solution. For the same time stepping, the coupled algorithm overestimation is much lower (see Fig. 16). Even if it is not the case here, the overestimation of the pressure $P_l$ by the fractional step algorithm could lead to the violation of the relaxation conditions detailed in [42]. In addition, when case 3 is computed with a time step $\Delta t = 10^{-3}$ s, the fractional step algorithm is unable to return to pressure equilibrium, and even stops just before $t = 0.02$ s (see Figs. 17 and 18). The temperature profiles of the liquid water and vapor, computed with the fractional step algorithm and the coupled algorithm, are given in Figures 19 and 20 respectively.

A convergence study is presented below. The error $E_\Psi(t, \Delta t)$ is defined as in the liquid gas section (117). The speed of convergence is close to one (see Fig. 21) for the two approaches, as expected. Note that the value of the error for the fractional step algorithm is about one hundred times bigger for the pressure $P_l$ than the one obtained with the coupled algorithm.

Besides, the ratio of computational costs is in the range [5, 12] in favour of the coupled algorithm, for a given $\Delta t$, see Table 2. Moreover, as mentioned before, the fractional step algorithm even blows up on coarse meshes.
Figure 15. Evolution of $P_l$ in case 3 computed with the fractional step algorithm. $\tau_p = 10^{-5} \text{ s}$, $\tau_T = 10^{-4} \text{ s}$, $\tau_m = 10^{-6} \text{ s}$. The initial conditions are given in Appendix A.

Figure 16. Evolution of $P_l$ in case 3 computed with the coupled algorithm. $\tau_p = 10^{-5} \text{ s}$, $\tau_T = 10^{-4} \text{ s}$, $\tau_m = 10^{-6} \text{ s}$. The initial conditions are given in Appendix A.

3.2.3. Application: One dimensional shock tube in vapour with a cloud of water droplets

The aim of this section is to test the coupled algorithm for a mixture of liquid water and its vapour. The application test case is composed of a one dimensional shock tube in vapour. At $t = 0$, a cloud of water droplets lies inside a portion of the tube. The initial conditions along the tube are set as follows:
Figure 17. Evolution of $\Delta P$ in case 3 computed with the fractional step algorithm. $\tau_P = 10^{-5}$ s, $\tau_T = 10^{-4}$ s, $\tau_m = 10^{-6}$ s. The initial conditions are given in Appendix A.

Figure 18. Evolution of $\Delta P$ in case 3 computed with the coupled algorithm. $\tau_P = 10^{-5}$ s, $\tau_T = 10^{-4}$ s, $\tau_m = 10^{-6}$ s. The initial conditions are given in Appendix A.
Figure 19. Evolution of $T_I$ and $T_v$ in case 3 computed with the fractional step algorithm. $\tau_P = 10^{-5}$ s, $\tau_T = 10^{-4}$ s, $\tau_m = 10^{-6}$ s. The initial conditions are given in Appendix A.

Figure 20. Evolution of $T_I$ and $T_v$ in case 3 computed with the coupled algorithm. $\tau_P = 10^{-5}$ s, $\tau_T = 10^{-4}$ s, $\tau_m = 10^{-6}$ s. The initial conditions are given in Appendix A.
Figure 21. Homogeneous case: convergence curve for case 2: $\tau_P = 10^{-5}$ s, $\tau_T = 10^{-3}$ s, $\tau_m = 5 \times 10^{-3}$ s. The initial conditions are given in Appendix A.

Three probes are set inside the tube:
- $S_1$ is located inside the initial vapour layer of the tube: $x = 1.77$ m.
- $S_2$ is located at the beginning of the initial cloud of water droplets: $x = 3.08$ m.
- $S_3$ is located in the middle of the initial zone of liquid – vapour mixture: $x = 3.20$ m.

Relaxation time scales and EOS coefficients are the same as those used for the convergence curves in Figure 21 and can be found in Appendix A, case 2. In this test case, the particles are supposed to be rigid.

As expected, the solution obtained in the homogeneous case is retrieved at station 3 in the first time steps, see Figures 22–24. Moreover, in this case, the pressure disequilibrium is substantial as $\Delta P$ can be four times larger than the initial pressure, see Figure 23. The temperature disequilibrium is also significant, as it is still about 70% of its initial value after the shock wave. The difference of velocities $\Delta U$ is also quite large, close to $600 \text{ m s}^{-1}$ right after the shock wave.

Remark 5. Eventually, it is also worth noting that the fractional step algorithm fails to compute an approximate solution of this test case.

4. Conclusion

When focusing on the class of liquid–gas flow models considered here, conditions (43)–(45) are the true conditions that guarantee the effective relaxation process. For most EOS, conditions (44) and (45) are not trivial and have to be numerically tested inside the code. In most cases, conditions (44) and (45) also involve initial conditions. For liquid–vapour flows, four conditions arise, which also involve EOS and initial conditions.
Figure 22. Evolution of $P_{\text{mix}}$ for two meshes including 1000 cells and 10 000 cells.

Figure 23. Evolution of $P_t$ and $P_v$ at station 3 with the initial condition of case 2. A mesh of 10 000 cells has been used.
The coupled algorithm, which has been introduced for the treatment of the sub-system associated with the source terms (34), is grounded on the analysis of relaxation effects. This new strategy has been compared with the classical fractional step method. The comparison is clearly in favour of the coupled algorithm, as it was expected, and this is particularly true when rather coarse time steps are considered, or equivalently on coarse “industrial” meshes. Indeed, the coupled algorithm is more stable, especially in the liquid–vapour case. The latter algorithm also provides a higher accuracy for a given mesh size, and a lower computational cost for a comparable accuracy, than the fractional step approach. Moreover, some particular test cases exhibit a rather strange behaviour of the fractional approach, and this might in some sense be compared with what happens when computing shallow-water equations with well-balanced schemes versus the fractional step method. It also clearly arises that mass transfer terms have a huge impact on the practical stability of the whole algorithm.

In addition, substantial values of $\Delta U$, $\Delta P$ and $\Delta T$ can be observed in the transient regime throughout this paper, which pleads against any hypothesis of instantaneous return-to-equilibrium, for both mechanical and thermodynamic quantities. A posteriori, it also justifies the investigation of the relaxation process.

Of course, higher-order time schemes, such as the Radau V method presented in [65], might be used to improve the accuracy of the coupled algorithm, but this lies beyond the scope of the present work. Eventually, relaxation solvers such as those presented in [9,16] could improve both the accuracy and the computational cost when accounting for convective terms (61).

Appendix B. Velocity relaxation algorithm

During this step, system (5) become, for $k \in \{g, v\}$:

\[
\begin{align*}
\hat{\tau}_l \alpha_l & = 0 \\
\hat{\tau}_l m_l & = 0 \\
m_l \hat{\tau}_l U_l & = -d(W) \Delta U \\
\hat{\tau}_l (\alpha_l E_l) & = -d(W) \frac{U_l + U_k}{2} \Delta U \\
\hat{\tau}_l (m_l + m_k) & = 0 \\
\hat{\tau}_l (m_l U_l + m_k U_k) & = 0 \\
\hat{\tau}_l (\alpha_l E_l + \alpha_k E_k) & = 0.
\end{align*}
\] (B.1)

The following algorithm is taken from [25].

Velocity relaxation algorithm

**Step 1.** Compute $U_l^{n+1-}$ and $U_k^{n+1-}$ as:

\[
\begin{align*}
U_l^{n+1-} & = U_l^{n+1*} - \Delta U^{n+1*} \frac{m_k^{n+1*} (1 - \frac{\Delta l}{\tau_l^{n+1*}})}{m_k^{n+1*} + m_l^{n+1*}} \\
U_k^{n+1-} & = U_l^{n+1*} + \Delta U^{n+1*} \frac{m_k^{n+1*} (1 - \frac{\Delta l}{\tau_l^{n+1*}})}{m_k^{n+1*} + m_l^{n+1*}}.
\end{align*}
\] (B.2)
Step 2. Compute $(m_\ell e_\ell)^{n+1}$ and $(m_k e_k)^{n+1}$ as:

$$
\begin{align*}
(m_\ell e_\ell)^{n+1} &= (m_\ell e_\ell)^{n+1} + \frac{m_\ell^{n+1} e_\ell^{n+1} (\Delta U^{n+1})^2}{2} \left( 1 - e^{-\frac{2\Delta t}{U^{n+1}}} \right) \\
(m_k e_k)^{n+1} &= (m_k e_k)^{n+1}.
\end{align*}
$$

(B.3)

Step 3. Update the total energies as:

$$
\begin{align*}
(\alpha_\ell E_\ell)^{n+1} &= (m_\ell e_\ell)^{n+1} + \frac{1}{2} m_\ell^{n+1} (U_\ell^{n+1})^2 \\
(\alpha_k E_k)^{n+1} &= (\alpha_k E_k)^{n+1} + (\alpha_\ell E_\ell)^{n+1} - (\alpha_\ell E_\ell)^{n+1}.
\end{align*}
$$

(B.4)

Appendix C. Interfacial area

The definition of the interfacial area of the water phase is recalled:

$$\mathcal{A} = 6 \alpha_l D_d \tag{C.1}\text{.}$$

Its equation of evolution is supposed to be:

$$\frac{\partial \mathcal{A}}{\partial t} + \nabla (\mathcal{A} U_\ell) = g(\mathcal{A}, W) \tag{C.2}\text{,}$$

with:

$$g(\mathcal{A}, W) = C_0 \mathcal{A}^2 \left( \frac{\rho_l}{\rho_g} \right)^{1/2} U_\ell f(We) \tag{C.3}\text{,}$$

where $U_\ell = \|U_\ell - U_g\|$ and $We$ the Weber number define as follows:

$$We = \frac{\rho_g U_\ell^2 D_d}{\sigma_d} \tag{C.4}$$

with $\sigma_d = 73 \times 10^{-3} (N.m^{-1})$ a reference surface tension [54]. Moreover $f(We)$ is defined as:

$$f(We) = 1, \text{ if } We > We_c; \text{ } f(We) = 0 \text{ otherwise} \tag{C.5}\text{.}$$

where $We_c$ is called the critical Weber.

Adding this new equation does not change the structure and properties of the global system (5) according to [5]. Hence, it is chosen for the simulation. The numerical scheme used to simulate (C.2) is detailed in [5]. It consists of a fractional step method, splitting the convective part and the source term part. Those two steps will respectively be inserted inside the explicit simulation step of the convective part of system (5) and the implicit simulation of the source terms of the same system.

Appendix D. Mass transfer algorithm

During this step, system (5) writes as:

$$\begin{align*}
\frac{\partial t}{\partial t} &\alpha_v = 0 \\
\frac{\partial t}{\partial t} m_v &= \Gamma_v \\
\frac{\partial t}{\partial t} (m_v U_v) &= \frac{U_\ell + U_g}{2} \Gamma_v \\
\frac{\partial t}{\partial t} (\alpha_v E_v) &= \frac{U_\ell U_g}{2} \Gamma_v \\
\frac{\partial t}{\partial t} (m_\ell + m_v) &= 0 \\
\frac{\partial t}{\partial t} (m_\ell U_\ell + m_v U_v) &= 0 \\
\frac{\partial t}{\partial t} (\alpha_\ell E_\ell + \alpha_v E_v) &= 0
\end{align*}\tag{D.1}$$

with:

\[
\Gamma_v = \frac{1}{\Gamma_0 m_l + m_g} \Delta \mu. \tag{D.2}
\]

From (D.1), a conservation law of the internal energies is obtained during this step:

\[
\begin{cases}
\partial_t \left( m_v \epsilon_v \right) = 0 \\
\partial_t \left( m_l \epsilon_l \right) = 0
\end{cases} \tag{D.3}
\]

which implies that:

\[
\Gamma_v = \frac{\partial_t \left( m_v \epsilon_v \right)}{m_l \epsilon_l}. \tag{D.4}
\]

The following algorithm is taken from [18]. A detailed version in French is also available in [45].

**Mass transfer algorithm**

**Step 1.** Compute \( m_l^{n+1*} \), solution of:

\[
m_l^{n+1*} = m_l^{n*} - \Delta t \Gamma_v \left( m_l^{n+1*} \right) \tag{D.5}
\]

and update \( m_v^{n+1*} = m_v^{n*} + m_l^{n+1*} - m_l^{n+1*} \).

**Step 2.** Compute \( U_l^{n+1*} \) and \( U_v^{n+1*} \) as:

\[
\begin{cases}
(m_l U_l)^{n+1*} = (m_l U_l)^{n*} - \Delta t \Gamma_l \left( (m_l^{n+1*})^{n+1} U_l^{n+1*} + U_v^{n+1*} \right) \\
(m_v U_v)^{n+1*} = (m_v U_v)^{n*} + (m_l U_l)^{n*} - (m_l U_l)^{n+1*}
\end{cases} \tag{D.6}
\]

**Step 3.** Update the total energies as:

\[
\begin{cases}
(\alpha_l E_l)^{n+1*} = (\alpha_l E_l)^{n*} - \Delta t \Gamma_l \left( (m_l^{n+1*})^{n+1} U_l^{n+1*} U_v^{n+1*} \right) \\
(\alpha_v E_v)^{n+1*} = (\alpha_v E_v)^{n*} + (\alpha_l E_l)^{n*} - (\alpha_l E_l)^{n+1*}
\end{cases} \tag{D.7}
\]

**APPENDIX E. COEFFICIENTS OF THE MATRIX \( \mathcal{R}_{PT\mu} \)**

Matrix \( \mathcal{R}_{PT\mu}(W) \in R_{3x3} \) is as follow, see [42]:

\[
\mathcal{R}_{PT\mu}(W) = \begin{pmatrix}
a_{PP}^v(W) & a_{PT}^v(W) & a_{P\mu}^v(W) \\
a_{P\mu}^v(W) & a_{PT}^v(W) & a_{P\mu}^v(W) \\
a_{\mu P}^v(W) & a_{\mu T}^v(W) & a_{\mu\mu}^v(W)
\end{pmatrix}. \tag{E.1}
\]

The above mentioned coefficients are as follows:

\[
\begin{align*}
a_{PP}^v(W) &= K(W) \left( A_l + A_v - \frac{\Delta P}{m_l \bar{e}_{\mu_l}(\epsilon_l)_{\mu_l}} \right) \\
a_{PT}^v(W) &= q(W) \left( \frac{1}{m_l \bar{e}_{T_l}(\epsilon_l)_{\mu_l}} + \frac{1}{m_v \bar{e}_{T_v}(\epsilon_v)_{\mu_v}} \right) \\
a_{P\mu}^v(W) &= \Lambda(W) \left( -\epsilon_{l+\nu_l} \bar{\mu}_{\mu_l}(\epsilon_l)_{\mu_l} - \frac{\epsilon_{\nu_v} + \nu_v \bar{\mu}_{\nu_v}(\epsilon_v)_{\nu_v}}{m_v \bar{e}_{T_v}(\epsilon_v)_{\mu_v}} \right)
\end{align*} \tag{E.2}
\]

and:

\[
\begin{align*}
a_{PV}^v(W) &= K(W) \left( \frac{P_v - \rho_v \bar{e}_{\mu_l}(\epsilon_l)_{\mu_l}}{m_l \bar{e}_{T_l}(\epsilon_l)_{\mu_l}} + \frac{P_v - \rho_v \bar{e}_{T_v}(\epsilon_v)_{\nu_v}}{m_v \bar{e}_{T_v}(\epsilon_v)_{\nu_v}} \right) \\
a_{PT}^v(W) &= q(W) \left( \frac{1}{m_l \bar{e}_{T_l}(\epsilon_l)_{\mu_l}} + \frac{1}{m_v \bar{e}_{T_v}(\epsilon_v)_{\nu_v}} \right) \\
a_{P\mu}^v(W) &= \Lambda(W) \left( -\epsilon_{l+\nu_l} \bar{\mu}_{\mu_l}(\epsilon_l)_{\mu_l} + \frac{-\epsilon_{\nu_v} + \nu_v \bar{\mu}_{\nu_v}(\epsilon_v)_{\nu_v}}{m_v \bar{e}_{T_v}(\epsilon_v)_{\mu_v}} \right)
\end{align*} \tag{E.3}
\]
for $k$th $P$ norm of the error on the pressure is greater than 100, within a very wide range of time steps. This ratio of errors decreases when $\tau$ EOS coefficients). Figure G.3 highlights that the ratio of errors between the two methods, for a given time step, is greater than 100, within a very wide range of time steps. This ratio of errors decreases when $\tau$ EOS coefficients).

Eventually, setting:

$$F_k = \left( \frac{1}{\rho_k \partial P_k(\epsilon_k)|_{\rho_k}} - \frac{h_k}{T_k \partial T_k(\epsilon_k)|_{\rho_k}} \right)$$

$$G_k = \frac{h_k}{T_k \partial T_k(\epsilon_k)|_{\rho_k}}(\epsilon_k + \rho_k \partial \rho_k(\epsilon_k)|_{\rho_k}) - \frac{1}{\rho_k \partial \rho_k(\epsilon_k)|_{\rho_k}}(\epsilon_k + \rho_k \partial \rho_k(\epsilon_k)|_{\rho_k})$$

$$H_k = \frac{h_k}{T_k \partial T_k(\epsilon_k)|_{\rho_k}}(-P_g + \rho_k \partial \rho_k(\epsilon_k)|_{\rho_k}) - \frac{1}{\rho_k \partial \rho_k(\epsilon_k)|_{\rho_k}}(-P_g + \rho_k \partial \rho_k(\epsilon_k)|_{\rho_k})$$

for $k = l, v$, we have:

$$\begin{align*}
 a_{\mu \rho}^l(W) &= K(W)\left( \frac{H_g}{m_1 T_1} + \frac{H_p}{m_2 T_2} \right), \\
 a_{\mu T}^l(W) &= q(W)\left( \frac{F_1}{m_1 T_1} + \frac{F_2}{m_2 T_2} \right), \\
 a_{\mu \mu}^l(W) &= \Lambda(W)\left( \frac{G_1}{m_1 T_1} + \frac{G_2}{m_2 T_2} \right).
\end{align*}$$

The relaxation process over time is guaranteed if the three fundamentals minors are positive [42].

**APPENDIX F. THE RIP CONDITION**

We consider the class of gas–liquid flow models discussed in Section 3, thus focusing on immiscible components. We assume some initial condition $W^0(x) = W(x, t = 0)$, such that:

$$U_k(x, t = 0) = 0,$$

and with uniform pressure and temperature fields:

$$P_k(x, t = 0) = P_0; \quad T_k(x, t = 0) = T_0.$$

The flow will remain steady, if:

$$\partial_t(\psi)(x, t = 0) = 0$$

whatever $\psi$ is.

Obviously, the source terms vanish, and we get:

$$\begin{align*}
 \partial_t(\alpha_k)(x, t = 0) &= 0; \\
 \partial_t(m_k)(x, t = 0) &= 0; \\
 \partial_t(m_k U_k)(x, t = 0) + P_0 \nabla \alpha_k^0 - \Pi_k(W^0) \nabla \alpha_k^0 &= 0; \\
 \partial_t(\alpha_k E_k)(x, t = 0) &= 0.
\end{align*}$$

Thus the flow will remain steady if:

$$(P_0 - \Pi_k(W^0)) \nabla \alpha_k^0 = 0$$

whatever the initial profile of $\alpha_k^0$ is, or in other words:

$$\Pi_k(W^0) = P_0.$$

This will be called the Realizable Interfacial Pressure (RIP) condition.

**APPENDIX G. BEHAVIOUR OF THE FRACTIONAL STEP AND COUPLED APPROACHES WHEN $\frac{\tau_p}{\tau_T}$ TENDS TO ZERO**

In this appendix, the temperature relaxation time scale is set to: $\tau_T = 10^{-3}$ s. Figures G.1–G.3 show the $L^1$ norm of the error on the pressure $P_0$, at $t = 0.001$ s in case 1 (see Appendix A for details on initial data and EOS coefficients). Figure G.3 highlights that the ratio of errors between the two methods, for a given time step, is greater than 100, within a very wide range of time steps. This ratio of errors decreases when $\frac{\tau_p}{\tau_T} = 1$, see Figure G.1, but it is still in favour of the coupled approach.
Figure G.1. Convergence curve in case 1 with $\frac{\tau_L}{\tau_T} = 1$.

Figure G.2. Convergence curve in case 1 with $\frac{\tau_L}{\tau_T} = 10^{-4}$. 

Here, Chauvin experiment [11] is simulated with rigid particles assuming constant interfacial area, associated with constant particle diameter: $D_d = 500 \, \mu m$. The initial conditions and thermodynamic coefficients are recalled in Appendix A. The relaxation time scales are the same as those used in Section 3.1.3.

We recall that for collapsible droplets, as in the experiment, a pressure drop occurs right after the incident shock wave, as expected when droplet atomization arises, see [31]. The simulation captures this phenomenon quite well, see Figure 10.

On the other hand, Figure H.1 shows that with rigid particles, the simulation exhibits a slow increase of the total pressure after the incident shock wave. Similar results have already been exhibited in [6, 12].
